#### CERTIFICATE

This is to certify that the thesis entitled
'' FLOW OVER LONGITUDINAL BAR BOTTOM-RACKS' submitted
by Shri Shree Kant Shukla in partial fulfilment of the
requirements for the degree of Master of Technology at
Indian Institute of Technology, Kanpur is a record of
bonafied research work carried out by him under my
supervision and guidance. The work embodied in this
thesis has not been submitted elsewhere for a degree.

Dated: April 15, 1987

1. Duloamanga

Dr. K. Subramanya Professor

Dept. of Civil Engineering
Indian Institute of Technology
KANPUR

#### **ACKNOWLEDGEMENTS**

The author wishes to record his deep sense of gratitude to Dr. K. Subramanya for suggesting the problem and supervising the study covered in this thesis. The author is deeply indebted to him for his inspiring guidance. meticulous attention, constructive criticism and above all for his untiring devotion through out the tenure of this work.

Thanks are due to Sri Suresh Kumar, T.O., Sri N. Satyanarayana, T.O., and other staff of the Hydraulics Laboratory for their help in various phases of the experimental work.

The author is highly thankful to his wife, his borthers and some of his other relatives for their constant encouragement towards higher studies.

The author would also like to thank his friends,

A.K. Dixit , D.K. Singh, R.K. Pachauri, R.L. Rana, S.R. Singh

and Zagde for their help at certain important moments during
this work.

At the end, thanks due to all those who helped the author directly or indirectly during this work.

(Shree Kant Shukla)

### **ABSTRACT**

An experimental study of the hydraulic behaviour of longitudinal bar bottom-racks for different flow conditions and geometry of the rack has been carried out. The flow has been classified into five types viz, Al, A2, A3, Bl and B2, based on the approach flow condition and the effect of the tail water at the inlet. The Al, A3, and Bl flows have been studied in detail in the present work. The variation of the limiting inlet depth ratio with the opening area ratio of the rack has been determined in Al and Bl flows and enables one to predict whether the flow over the rack is fully submerged or not. A suitable coefficient of discharge has been defined by using a working specific energy head and the orifice type of flow. Important flow and rack parameters affecting the coefficient of discharge  $C_d$  have been identified. The flow parameter in Alflows was found to have negligible effect on  $C_d$ , while it has considerable effect in A3 and B1 flows. The variation of the discharge diversion in a rack has also been studied with pertinent flow and rack parameters for Al and Bl flows separately.

The energy loss was found to be substantial particularly in Al and Bl flows, though it was negligible in A3 flows. The energy slope over the rack has been studied with prominent flow and rack parameters and approximate relationships have been obtained for evaluating the energy slope in

Al and Bl flows. This information will be useful in realistic estimation of water surveface profiles over a rack.

The findings of the present study provides basic data for effective and rational design of trench weirs.

#### . CHAPTER I

#### INTRODUCTION

### 1.1 Bottom-Racks and Their Applications:

Hydraulic structures are used to utilise effectively the available water-resources. Plans for the development of water-resources demand improved performance of hydraulic structures to harness river waters. Bottom-racks, also called as bottom-intakes, are hydraulic structures used to divert the flow in open-channels. Such bottom-intakes find diverse applications in different fields of hydraulic engineering, particularly in diverting water from mountanous streams. Some of the applications of bottom intakes are listed below.

(1) An application of bottom-intake which is becoming more popular nowadays because of the economy in it's use as horizontal trash racks in the hydro-power plants located on mountaneous streams. Such a structure, besides being simple in construction, eliminates the possible damage during floods to which any raised crest across the streams used for flow diversion would be susceptible.

Such bottom-intakes in the streams are also known as '' Trench Weirs''. Some of the trench weir installations in India are:

(i) Two components of Binwa Hydroelectric project (H.P.) 2x3MW.

- (ii) Andhra Hydroelectric project (H.P.) 3x5.65MW.
- (iii) Bhaledh Nallah component of Baira-Siul Hydel Project 3x60 MW.
- (iv) Stakna Hydel project, Leh ( J and K).

Detailed information on Trench Weirs are available in Ref. (2,9).

- (2) In an irrigation canal system the surface runoff may some times be let into a canal and excess flow may be disposed off at some convenient location downstream to a suitable drainage. The bottom-racks can effectively be used for this purpose.
- (3) A very common use of bottom-racks is as '' Kerb-outlets' on the sides of main street to drain storm water into the subsurface drains. These outlets may be made up of horizontal or slightly inclined bottom racks.
- (4) Often, the bottom-racks are used as '' Skimmers ''
  when it is desired to reduce the volume of water to
  transport fish (1).
- (5) Bottom-rack can also be used in the sedimentation tanks to trap the debris in the grit chambers (11).
- (6) A bottom-intake structure designed for the use by the Government of Hong Kong to divert water from streams draining the Sai Kung Peninsula by a system of shafts and tunnels to a reservoir at high island is described in Ref.(14).

### 1.2 Different Kinds of Bottom-Racks:

Fig. 1.1 shows a typical definition sketch of a bottom-rack assembly. The bottom-racks can be classified into four categories on the basis of the nature of the rack as:

### (i) Transverse bar bottom-racks:

In these racks the bars are placed transverse to the direction of flow. The bars may be of circular, rectangular or of any special shape to meet the specific requirement. When the width of the stream is large compared to the length of rack, the installation of these racks may sometimes prove to be uneconomical because of the requirement of too lengthy bars.

### (ii) Longitudinal bar bottom-racks:

In these racks the bars are laid parallel to the direction of flow. The bars are of any convenient shape. These racks are convenient to install under field conditions, where the width of the stream is large compared to the length of the rack. All the trench weirs adopt this type of bottom-racks.

## (iii) Perforated plate bottom-racks:

Such racks are generally used in process industries,

These are plates having uniformly spaced or staggered circular
holes.

## (iv) Slots:

Slots are the limiting case of bottom-racks with all the bars removed.

Further to the above classification the bottomracks may be horizontal or inclined with reference to approach bed level of the channel.

The present investigation is confined to the study of horizontal longitudinal bar bottom-racks with circular bars only.

### 1.3. Hydraulics of Longitudinal Bar Bottom-Racks:

The flow over the bottom-rack is a spatially varied flow with decreasing discharge. The performance of a bottom rack depends upon the flow characteristics such as the amount of main flow, the state of flow approaching the rack and the geometric characteristics of the rack such as it's length, width, slope and the shape, width and spacing of the rack elements.

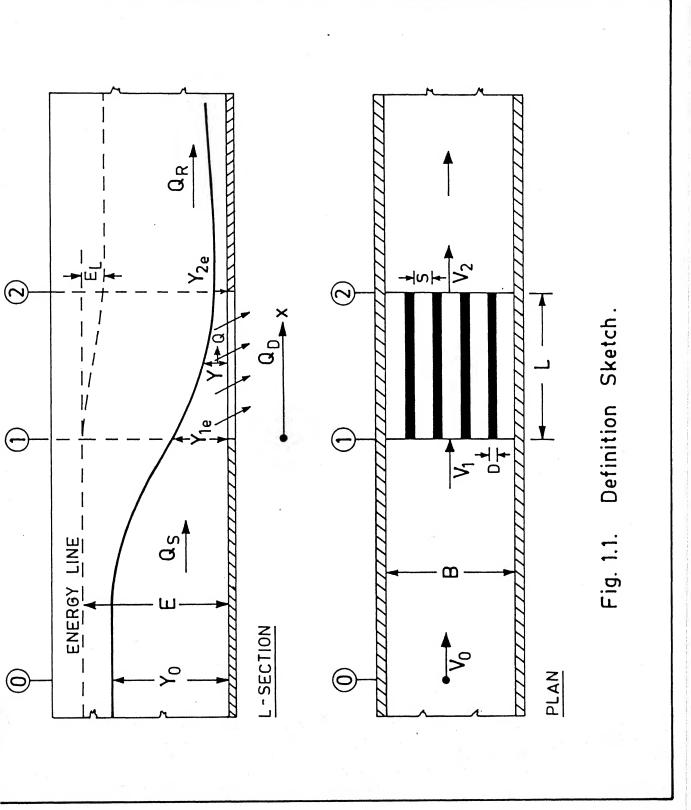

Fig. 1.1 is a definiton sketch of the flow over a horizontal longitudinal bar bottom-rack. The bars are made of circular rods of diameter D. The main variables involved in the problem are:

## (a) Flow characteristics:

Rate of approach flow  ${\bf Q_S},$  rate of diverted flow through the rack  ${\bf Q_D},$  state of approach flow, depths  ${\bf y_o}, {\bf y_{le}}$  and  ${\bf y_{2e}}.$ 

## (b) Geometry of the Rack:

This includes the length L, width B of the rack, the bar diameter D. and clear spacing S between bars.

### (c) The fluid properties:

Chiefly the dynamic viscosity  $\mu$  and mass density Q of water.

The basic hydraulic characteristics required to be predicted are:

- (i) To classify the different types of flows over the rack.
- (ii) A suitably defined coefficient of discharge C<sub>d</sub> and it's variation.
- (iii) The diversion ratio  $Q_{\rm D}/Q_{\rm S}$  of the rack.
- (iv) The water-surface profile over the rack.
- (v) The energy loss over the rack.

The above information will help one to design such a bottom-intake with help of known parameters.

## 1.4 The Present Study:

A study of the relevant literature on the topic of bottom-racks indicated that this field has received very little attention compared to it's practical importance. The available works while meagre are essentially for the slots (4,6,11,13) and transverse bar racks (7,8,10). The case of longitudinal bar bottom-racks while being important from practical point of view, has not received due attention and the studies are limited to a few exploratory investigations (3,5,14).

Keeping in mind the unsatisfactory information available, an experimental study, to prodict the hydraulic behaviour of horizontal longitudinal bar bottom-racks made up of circular bars, was designed to get maximum possible useful information within the limitations of available time. The present study includes different approach flow conditions and geometries of the rack. Some of the related works available in the literature have been compared with the data of present study. The arrangement of different topics in the thesis is as follows:

A critical review of the available literature has been presented in Chapter II. Chapter III contains the details of experiments and observations. Analysis of the data collected in the present study is given in Chapter IV. The various conclusions arising out of the present study have been collected in Chapter V. Certain recommendations for further studies on this topic are also listed in this Chapter.

Appendix I contains the basic as well as derived data of the present study. All the data are given in a convenient tabular form. In Appendix II a design procedure for a bottom-intake has been explained. A simple Fortran program has also been given for designing such a bottom-intake in practical situations where the approach flow conditions and the rate of flow to be diverted from the intake are known. A worked example also has been given by taking the data from model studies of Banu and Parai Khads of Himanchal Pradesh and results have been compared with their original recommended design.

#### CHAPTER II

#### A CRITICAL REVIEW OF LITERATURE

of spatially varied flow with decreasing discharge. Determination of the performance of a bottom-rack is a complex problem involving a large number of variables. Many investigations have been carried out with a view to evolve a proper design for a bottom-intake. Serious efforts to analyse and understand the phenomenon of flow over bottom-racks, however, have been devoted only since last three decades. Some of the important works are reviewed below:

## 2.1 Longitudinal Bar Bottom-Racks:

A retional approach to the problem of bottomracks was given by Mostkow(3). His experiments were conducted
on intakes having longitudinal bar bottom-racks. For the analysis, he assumed that for such bottom-racks the specific energy
of the flow all over the rack remains constant and is taken as
effective head causing the flow through the rack. The discharge per unit length of rack, by considering it as an orifice,
was given as

$$\left(-\frac{\mathrm{dQ}}{\mathrm{dx}}\right) = C_1 \in B \sqrt{2gE} \tag{2.1}$$

where  $C_1$  = coefficient of discharge of longitudinal bar bottom-racks and E = constant specific energy all over rack.

The differential equation of SVF for horizontal frictionless channel will be

$$\frac{dy}{dx} = \frac{Qy(-\frac{dQ}{dx})}{gB^2y^3-Q^2}$$
 (2.2)

Further, the discharge Q at any section is given by

$$Q = By \sqrt{2g(E-y)}$$
 (2.3)

substituting Eqs. (2.1) and (2.3) in (2.2) and integrating the final equation hence found, a equation for water surface profile was obtained as:

$$X = \frac{E}{C_1 \in} \left( \frac{y_{1e}}{E} \sqrt{1 - \frac{y_{1e}}{E}} - \frac{y}{E} \sqrt{1 - \frac{y}{E}} \right)$$
 (2.4)

The value of the coefficient  $C_1$  was assumed to be constant for a particular slope of the rack. He suggested that the value of  $C_1$  varies from 0.435, for a grade of 1 on 5, to 0.497, for a horizontal slope of the rack.

Noseda (5) has analytically studied the characteristics of a longitudinal bar bottom-intake. His assumptions are similar to that of Mostkow, with an addition that the approach flow to the rack is critical. The discharge per unit length of the rack was defined as

$$\left(-\frac{dQ}{dx}\right) = C_n \in B \sqrt{2gy} \tag{2.5}$$

where  $C_{n}=\text{coefficient}$  of discharge . The critical approach flow was given as

$$Q_{S}^{2} = gB^{3} y_{1e}^{3}$$
 (2.6)

The discharge diversion  ${\rm Q}_{\rm D}/{\rm Q}_{\rm S}$  from constant specific energy criteria and Eq. (2.6) is

$$\frac{Q_{D}}{Q_{S}} = 1 - \left[2\left(\frac{3}{2} - \frac{y_{2e}}{y_{1e}}\right)\right]^{1/2} \frac{y_{2e}}{y_{1e}}$$
 (2.7)

Eqs. (2.5) and (2.7) were combined and integrated to provide the relationship between two brink depths and length of the rack:

$$\sqrt{2} C_{n} \in L/y_{le} = \frac{3}{4\sqrt{2}} \left( \sin^{-1}(1/3) - \sin^{-1}(\frac{4y_{2e}}{3y_{le}} - 1) + \frac{3}{2} \left( 1 - (\frac{3y_{2e}}{y_{le}} - \frac{2y_{2e}^{2}}{y_{le}^{2}})^{-1/2} \right) \tag{2.8}$$

Finally, the general diversion characteristics relating the diverted flow and the stream flow was derived as a plot, using:

$$(\sqrt{2} \ C_n \in L/\gamma_{1e})^{-3/2} = \frac{Q_S/B}{g^{1/2}(\sqrt{2} \in C_n)^{3/2}L^{3/2}}$$
 (2.9)

Naseda suggested that  $C_n$  is independent of stream flow  $Q_{\S}$  and aspect ratio of the bars (D/L). Assuming  $C_n$  as 0.815 for a given rack geometry and  $y_{le}, y_{2e}$  with the help of above Eqs. (2.7,2.8,2.9) a design chart as a plot of

$$\frac{Q_{D}/B}{g^{1/2}(\sqrt{2} \in C_{D})^{3/2} L^{3/2}} Vs \frac{Q_{S}/B}{g^{1/2}(\sqrt{2} \in C_{D})^{3/2} L^{3/2}} has been$$

recommended by Noseda to study the diversion characteristics.

White, et al (14) conducted model tests and compared the performance of bottom-intakes having different

length of bars, bar spacing, the transverse slope of the top surface of the bars and analysed the data on the basis of Noseda's work. The tests were conducted on racks made of longitudinal bars with special sloping top surfaces. Racks were kept at a constant longitudinal slope of 1 vertical on 5 horizontal. In these tests the value of € ranged from 0.167 to 0.333 and L/w from 6 to 10 where w= width of rack bars. This study has shown that C<sub>n</sub> is not independent of stream flow as suggested by Noseda. A design chart based on the model tests, as a plot of  $\frac{Q_S}{BL \in V | GW}$  Vs  $\frac{Q_D}{BL \in V | GW}$ valid for 6  $<\frac{I}{w}$  < 10; 0.167<E< 0.333 and critical approach flow to the rack only has beengiven by them. Further, regarding the shape of bars white, et al suggested that a '' no flow rejection'' along the top of bars at lower stream flows can be achieved by providing the transverse top surface slope on the bars, having value between 1 in 3 to 1 in 2.

## 2.2 Transverse Bar Bottom-Racks:

Subramanya and Sengupta (8,10) have conducted an extensive experimental study on the flow over transverse bar bottom-racks. The racks were made of rectangular bars of width w. It was shown that Mostkow's coefficient of discharge  $C_1$  depends upon the approach state of flow, viz whether subcritical or supercritical and on the aspect ratio w/L of bars. When the approach flow is supercritical,  $C_1$  varies significantly with the area factor. The coefficient  $C_1$  decreases as the approach flow Froude number is increased and the influence

of w/L is less pronounced. The same trend appears to exist when the approach flow is subcritical, though w/L has more pronounced effect on the value of  $C_1$ . Further, it was found that value of  $C_1$  is large for subcritical flows than for supercritical flows. They have not studied the effect of inclination of the rack on  $C_1$ . The assumption of constant specific energy through out the rack length, for determination of the water surface profiles, is questionable.

Rangaraju, et al (7) studied the flow over bottom-racks comprising of transverse circular bars. The experimental study was limited to subcritical approach flows only. A set of equations relating the length of the rack to hydraulic parameters and empirical relations for the contraction coefficient as well as the discharge coefficient have been proposed. It has been shown that the coefficient of contraction is mainly the function of Reynolds number of the approach flow, Froude number of the flow over rack and the opening area ratio of the rack. Further, it was shown that there is an energy loss over the rack which ranges from 20 percent to 50 percent of the initial specific energy. A method of computing the discharge through-racks and the depths at the inlet and exit has been proposed.

## 2.3 <u>Perforate Plate Bottom-Racks</u>:

An analytical and experimental study conducted by Mostkow (3), is perhaps the major work available for perforated plate bottom-racks. For the analysis, he assumed that the effective head causing the flow is equal to the

depth of flow over the rack. The outflow discharge per unit length through the rack, was presented as

$$\left(-\frac{dQ}{dx}\right) = C_2 \in B \sqrt{2gy} \tag{2.10}$$

where  $C_2$  = coefficient of discharge for perforated plate bottomracks. The differential equation of SVF assuming the channel to be horizontal and frictionless, will be

$$\frac{dy}{dx} = \frac{Qy \left(-\frac{dQ}{dx}\right)}{gB^2y^3 - Q^2}$$
 (2.11)

substituting Eqs (2.16) and (2.3) in Eq. (2.16) and integrating by using the boundary condition  $y = y_{1e}$  at X = 0, yields the SVF prafile for perforared plate bottom-racks as

$$X = \frac{E}{E \cdot C_2} \left[ \frac{1}{2} \left( \cos^{-1} \sqrt{\frac{y}{E}} - \cos^{-1} \sqrt{\frac{y_{1e}}{E}} \right) + \frac{3}{2} \left( \sqrt{\frac{y_{1e}}{E} (1 - \frac{y_{1e}}{E})} - \sqrt{\frac{y}{E} (1 - \frac{y}{E})} \right) \right]$$
(2.12)

Mostkow (3) found that  $C_2$  is constant for a particular slope of the rack and varies from 0.750, for a grade of 1 on 5, to 0.800, for a horizontal slope of the rack. Sengupta (8) has shown the variation of  $C_2$  with  $F_1$ ,  $\in$  and w/L for supercritical approach flows. Subramanya (10) suggested that  $C_2$  could be expected to be given by

$$C_{2}=fn \ (F_{1}, \in , \lambda_{1}, \lambda_{2})$$
 (2.13)

where  $\lambda_1$  = a hole spacing parameter and  $\lambda_2$  = a hole arrangement parameter. No extensive analysis and experimental study is available regarding the variation of  $C_2$ .

## 2.4 <u>Slots</u>:

Studies on hydraulic characteristics of bottom-slots have been reported by Venkataraman (4,11,13) and Ramamurthy (6). Venkataraman, et al (4) have conducted an analytical and experimental study of the flow with a slot spanning the entire width of the channel. Defining the coefficient of discharge through the slot  $C_{\rm dv}$  as:

$$C_{dv} = \frac{Q_D}{BL \sqrt{2gE_1}}$$
 (2.14)

where  $E_{l}=$  specific energy of the flow at inlet. An expression for the variation of  $C_{\rm dv}$  has been obtained as

$$C_{dv} = 0.611 \sqrt{1 - (V_1^2/2gE_1)}$$
 (2.15)

The Equation 2.15 was also verified experimentally for subcritical as well supercritical approach flows. A momentum formulation for the brink depth ratio  $y_{1e}/y_{2e}$  has been proposed. The ratio  $Q_{D}/Q_{S}$  is defined as performance factor of the slot and is found to be a function of  $L/y_{c}$  given as:

$$\frac{Q_{\rm D}}{Q_{\rm S}} = 0.59 \, (L/y_{\rm c}) + 0.04 \, (L/y_{\rm c})^2 \qquad (2.16)$$

Venkataraman (11,13) defined another coefficient of discharge  $C_{
m dvl}$  as

$$C_{\text{dvl}} = \frac{Q_{\text{D}}}{BL \sqrt{2gy_{1e}}}$$
 (2.17)

and observed experimentally that it is invariant with  $F_1$  and  $y_{1e}/L$  but decreases with the increase in length L of the opening.

Ramamurthy, et al (6) based on two dimensional channel outlet model and experimental data, presented a functional relationship between the discharge coefficient  $C_{dr}$  and the velocity parameter  $\eta_1$  with  $\frac{L}{y_{1e}}$  as the group parameter for the floor slot discharge, as

$$C_{dr} = 0.611 + C_{1r}\eta_{1}^{2} + C_{2r}\eta_{1}^{4} + C_{3r}\eta_{1}^{6} + \dots$$

$$0 < \frac{L}{y_{1e}} \le 1.0; \quad 0 < \eta_{1} \le 1.0$$
where  $C_{1r} = -0.538 + 0.254 \left(\frac{L}{y_{1e}}\right); \quad C_{2r} = 0.058 + 0.234 \left(\frac{L}{y_{1e}}\right)$ 
and  $C_{3r} = -0.129 - 0.489 \left(\frac{L}{y_{1e}}\right)$ 

$$1 + \frac{2P_{c}}{F_{1}^{2}} \qquad (2.20)$$

and  $P_c$  = Pressure correction factor for curvilinear flows = fn  $(L/y_c)$ 

Venkataraman, et al (12) have conducted on experimental study including all types of bottom-racks and slot. They have shown that the assumption of constant specific energy along the rack is confirmed for subcritical approach flows for racks with small openings. In all other cases an energy decrease along the rack was noted, but no detailed study in this regard is reported.

### 2.5 Conclusions:

On reviewing the available literature it is observed that results of many investigations are of very limited nature. Most of them belong to the category of transverse bar bottom-racks or slots. Further, the assumption of constant specific energy all over the rack is questionable. Since the parallel bar bottom-racks are important from the point of view of practical applications, it was felt worth while to conduct an experimental study for analysing the flow over such racks including as many variable as possible.

#### CHAPTER III

#### EXPERIMENTS AND OBSERVATIONS

### 3.1 Experimental Set-up:

To study the hydraulic behaviour of horizontal longitudinal bar bottom-racks, experiments were carried out in the hydraulic laboratory of the Indian Institute of Technology, Kanpur. The experiments were conducted in two flumes, Flumes A and B, with details as given below:

Table 3.1 Details of Flumes Used in the Experimental Study

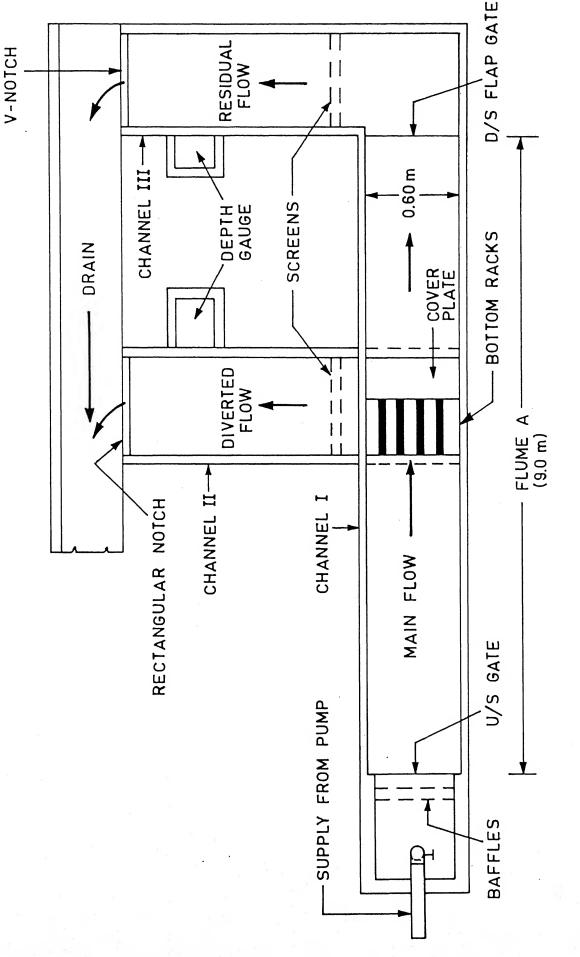

об на в достигности. В решервите и постоя от обще сорганизат обще со общения от постоя общения в сорганизация общения в решервите общения в достигности.	Flume A	Flume B
Width	0.60 m	0.15 m
Length	9.00 m	3.00 m
Туре	Non-recircula- ting	Partially -recir- culating
Bed	Horizontal and Smooth	Horizontal and Smooth
Side Walls	Masonry Side Walls	Plexi-glas Side Walls
Cross-Section	Rectangular	Rectangular
Max.Discharge <b>A</b> vailable	95 Liters/S	18 Liters/S
Upstream Control	Sluice Gate	Sluice Gate
Downstream Control	Bottom-hinged Flap Gate	Sluice Gate

The diverted flow through the rack in flume A was passed through channel No. II and measured by a rectangular-notch fitted at it's down stream end. Residual flow was passed

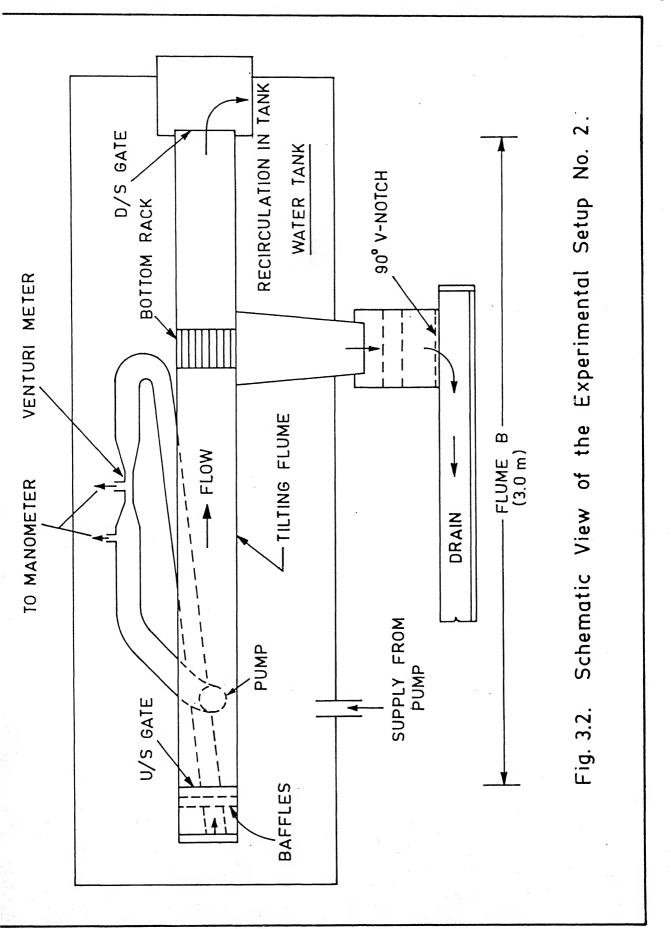

through channel No. III and measured by a V-Notch. The Notches were calibrated before starting the experiments. A schematic view of experimenal set up No. 1 for flume A is given in Fig. 3.1 The diverted flow through the rack in flume B was measured by a 90° V-Notch and the total stream flow was measured by a calibrated vinturimeter fitted in the supply pipe. For the head measurements in Notches, point guages with least count of 0.1 mm were used. A schematic view of experimental set up No.2 for flume B is given in Fig. 3.2.

In flume A, a slot having width B = 60 cm and Lenth L= 30 cm, was cut at a distance of 5 meter, from the upstream gate. The rack made of circular bars could be placed in this slot. The diameter D of the bars was kept 22 mm and the bars were placed at uniform clear spacing S. Keeping D = 22 mm as constant and varying the spacing S, four sets of racks were prepared having D/S ratios of 1.13, 2.05, 2.90 and 5.60. Then for the same rack by using a cover plate beneath and filling the gaps by cement mortar uniformly, the length of the rack was reduced to 15 cm, to achieve B/L=4.0. All the four rack sets having the D/S ratios mentioned above were also tested by making B/L = 4.0. With the available discharge and downstream control only supercritical approach flow could be obtained in flume A.

In flume B, a slot of width B=1.5 cm and length L=7.5 cm. was cut at a distance 2.56 meters, from the

Schematic View of the Experimental Setup No. 1. Fig. 3.1.

upstream gate. Circular bars of diameter 6 mm were used for all the rack assemblies and the bars were placed at uniform clear spacing. The spacing S was changed for different rack sets to achieve four sets of D/S ratios of 1.17, 1.89,3.33 and 5.50. With the help of small angles placed underneath the rack from both sides, the length could be reduced to 3.75 cm to achieve B/L = 4.0 for all the four rack sets. With the available discharge and downstream control only subcritical approach flow could be obtained in this flume. For the study of flow over a pure slot the flume B was chosen and a slot having B=15 cm was made. After this study, the slot length was reduced to 3.75 cm to get B/L = 4.0. When the whole flow was diverted within certain length of rack, this particular length was taken as L.

Table 3.2 Range of Parameters in the Experimental Study

Parameter	Range
D/S	1.13 to 5.60
$\epsilon$	0.157 to 0.487
B/L	2.00 and 4.00
D D	0.60 cm and 2.20 cm
F <sub>o</sub>	0.200 to 5.40
R <sub>er</sub>	$3.5x10^3$ to $3.5x10^4$
R <sub>eo</sub>	$1 \times 10^4$ to $1.95 \times 10^5$
$V_0^2/2gE_0$	0.02 to 0.95

### 3.2 Range of Parameters:

A total of 146 runs were conducted and the range of various parameters studied are shown in Table 3.2.

Where 
$$F_0 = \frac{V_0}{\sqrt{gy_0}} = \text{froude number of approach flow at}$$

$$\text{section (0) defined in Fig. 1.1.}$$

$$R_{eo} = \text{Approach flow Reynolds number at section (0)}$$

$$= \frac{Q_S}{S}$$

 $R_{er} = \frac{Q_{S}}{Q_{D} \times D}$   $R_{er} = \frac{R_{er}}{BL \in \mathcal{V}} = Reynolds number of the flow through the rack.$ 

 $\mathcal{V}$  = Kinematic viscosity of water; and

 $Q_D$  = Diverted flow through the rack.

The present study fairly covers the usual practical ranges of parameters used in the design of Trench weirs, as can be seen from Table 3.3 where some parameters corresponding to the design data of trench weirs are given.

## 3.3 Observations:

For a given rack in a flume, a series of experiments were conducted starting from the smallest discharge and gradually increasing it in steps till the maximum discharge capacity of the flume was reached. In a typical experiment the centre line depth of flow along the flume at different sections were measured with a movable point guage of least count 0.1 mm. On the basis of the water surface profiles that exist over the rack and the approach flow, the flows can be grossly classified into two categories viz, subcritical and supercritical approach flows.

<sup>\* =</sup> Data not available

## 3.3.1 Subcritical Approach Flow:

In the case of subcritical approach flow the depth of flow continuously decreases from upstream gate to the beginning of the rack. It is observed that the flow becomes supercritical at the inlet to the rack, hence producing a critical flow condition a little distance upstream from the inlet. The depth of flow decreases along the rack and super critical flow exists all over it. Downstream of the rack the depth increases slightly due to friction. Depending upon the tail water condition a jump may occur downstream to the rack. This jump may shift upstream and may form even in the middle of the rack itself. So long as the inlet

depth  $y_{le}$  is not affected by the jump (i.e. tail water) such flows are designated as 'Free flows'. When the jump shifts further upstream the inlet becomes submerjed and the flow becomes subcritical all along the channel. Thus, three types of flows could be identified in this category:

Al : Subcritical approach flow and super critical flow all over the rack. This is called 'subcritical approach free flow.'

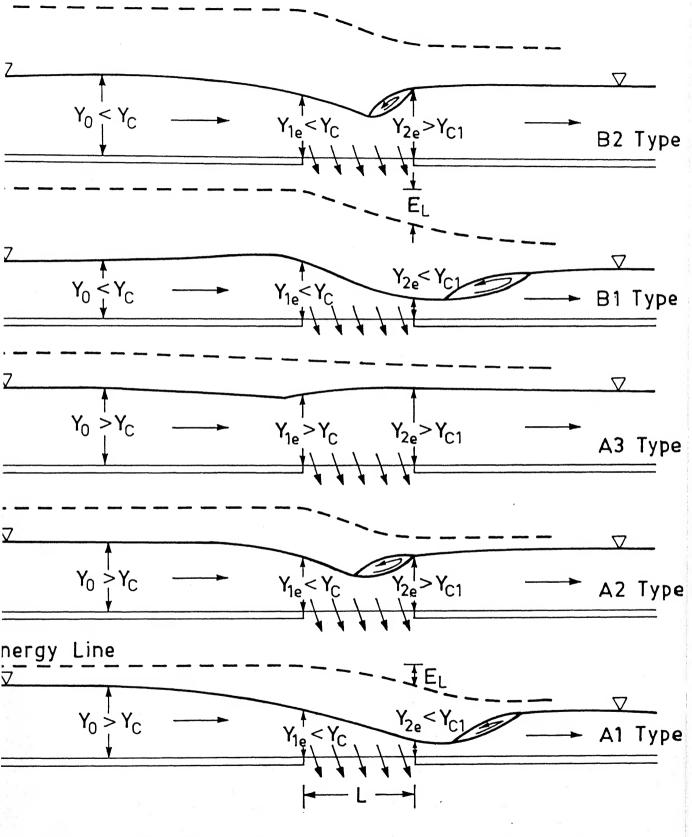

A2 : Subcritical approach and partial supercritical over the rack.

A3 : Subcritical flow all along the channel. This is called 'Subcritical approach submerged flow'.

All the three types of flows are shown in Fig. 3.3. In this figure  $y_{\rm c}$  is upstream critical depth and  $y_{\rm cl}$  stands for downstream critical depth.

### 3.3.2 Super Critical Approach Flows:

In the category of supercritical approach flows it was observed that for lower Froude numbers (say  $F_0$ =1.2) the water surface drops from the upstream gate to the beginning of the rack. The depth of flow decreases along the rack and the flow along it will also be supercritical. After the end of the rack the depth increases slightly due to friction. The same trend is observed for all the lower Froude numbers ( $R_0$ =1.0 to 1.4). But when the Froude number is more than about 2.0 the depth increases from upstream gate upto about

. 3.3. Classification of Different Types of Flows Over Bottom-racks.

the beginning of the rack due to high channel friction and drops down at the beginning of the rack. Depending upon the downstream control, a jump may some time occur downstream of the rack and may shift upstream to produce subcritical flow in the neighbourhood of inlet in the approach channel. Also it can be observed that for Froude numbers greater than 2.0 there is lesser difference between  $y_{2e}$  and  $y_{1e}$  compared to that in the Froude number range of 1.0 to 1.4. Thus two types of flows may be clearly identified:

- Bl : Supercritical approach flow and supercritical flow all over the rack.
- B2 : Super critical approach flow and partial subcritical over the rack.

B1 and B2 types of flows are shown in Fig. 3.3. Typical observed water surface profiles for different types of flows A1, A2 and A3 are shown in Fig. 3.4. Fig. 3.5 shows the profiles, all corresponding to B1 flows only. For a few runs the velocity profiles were also measured at certain sections of the channel. Some of the observed velocity profiles are shown in Fig. 3.6.

The present investigation is confined to the study of Al,A3 and Bl flows. The flow types A2 and B2 are beyond the scope of the present study in view of the complex flow situations. The data collected in Al, A3 and Bl flows are summarised in Appendix I.

#### CHAPTER IV

#### ANALYSIS

### 4.1 Study of The Limiting Inlet Depth:

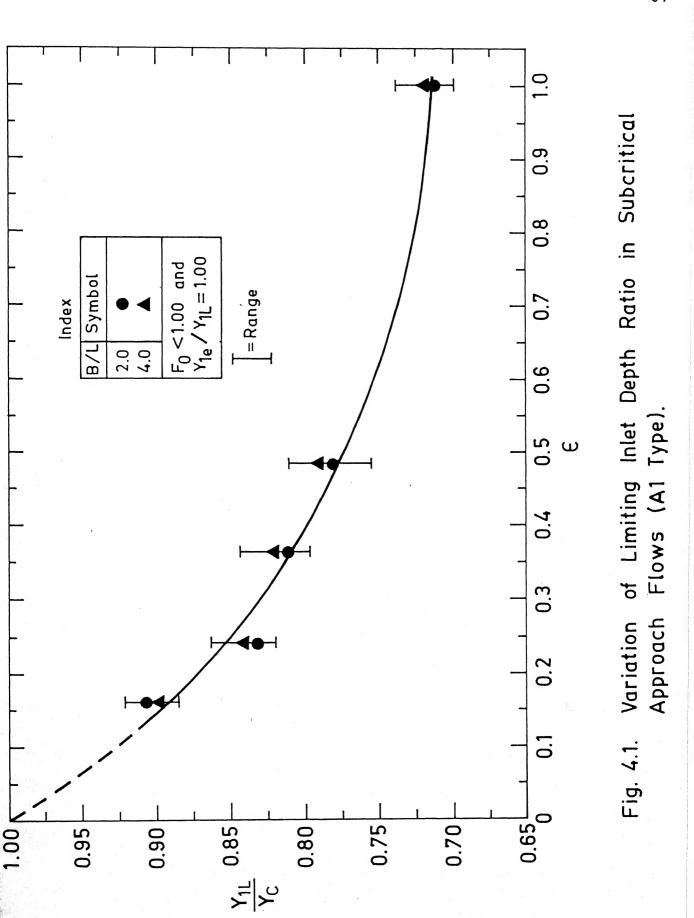

### 4.1.1 Subcritical Approach Flows:

As indicated earlier in section 3.3.1 and shown in Fig. 3.3, three types of flows (viz, Al,A2,A3) are possible for subcritical approach flow case. The limiting inlet depth  $y_{lL}$  is introduced with a view to differentiate the free and submerged flows. For Al and A2 types of flows the inlet depth  $y_{le}=y_{lL}$  and for A3 type of flow the inlet depth  $y_{le}>y_{lL}$ . In a subcritical flow with a sudden drop, the depth  $y_{lL}$  will be the end depth. For rectangular channels, subcritical flows it's value will be a constant at 0.715  $y_c$ . Also for any channel shape, in subcritical flows, the end depth ratio  $y_{lL}/y_c$  is independent of the Froude number (10). Hence, for Al type flows over longitudinal bar bottom-racks, the ratio  $y_{lL}/y_c$  can be represented as

$$\frac{Y_{1L}}{Y_{C}} = fn (B/L, \in)$$
 (4.1)

Fig. 4.1 shows the variation of the limiting inlet depth ratio  $\frac{y_{1L}}{y_c}$  with  $\in$  for B/L = 2.0 and 4.0. It is seen that

 $\frac{y_{1L}}{y_c}$  decreases with  $\epsilon$  and is unaffected by the value of B/L . A best fit equation for the variation of the limiting

inlet depth ratio was obtained as

$$\frac{y_{1L}}{y_{c}} = -0.215 \text{ Log} \in +0.715$$
 (4.2)

Eq.(4.2) is useful in determining the existence of A3 type flows.

### 4.1.2 <u>Supercritical Approach Flows</u>:

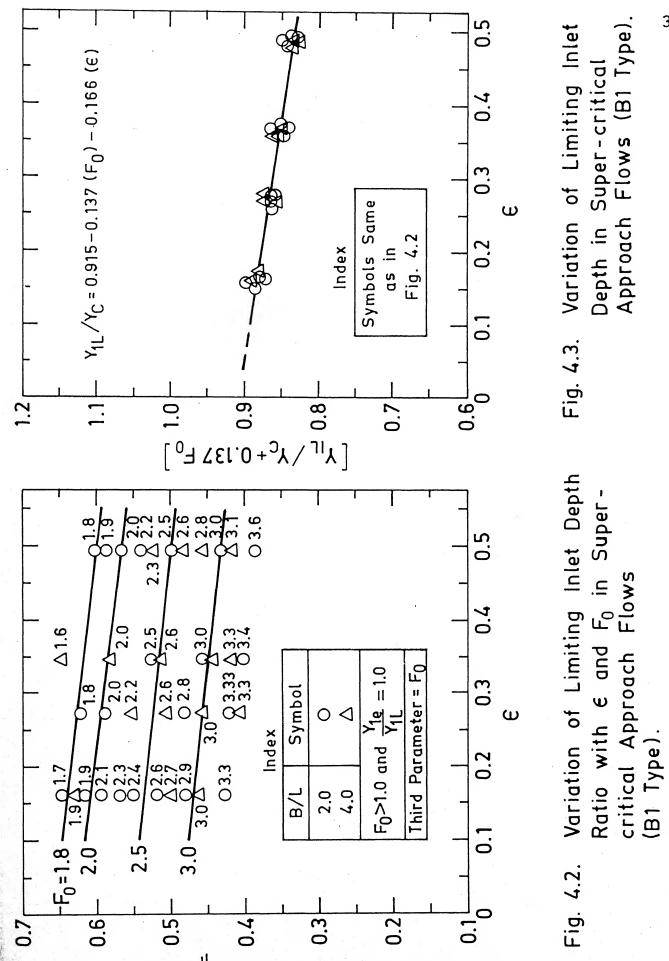

As indicated in section 3.3.2, in supercritical approach flows two types of flows over the rack are possible and these viz Bl and B2 type flows, are shown in Fig.3.3. From an analogy of end depths at sudden drops in supercritical flows, for Bl and B2 types of flows over racks  $\frac{y_{1L}}{y_c}$  can be expected to be a function of Froude number also and can be represented as

$$\frac{y_{1L}}{y_{c}} = fn (B/L, \in F_{o})$$
 (4.3)

Fig. 4.3 shows the variation of  $\frac{y_{1L}}{y_c}$  with  $\in$  and B/L, by taking  $F_o$  as a third parameter. It is seen that the B/L does not have any effect on  $\frac{y_{1L}}{y_c}$ . The effect of  $F_o$  on  $\frac{y_{1L}}{y_c}$  for a given  $\in$  was found to be related by a linear relationship and the relation between the three parameters found by the best fit technique is:

$$\frac{y_{1L}}{y_{c}} = 0.915 - 0.137 F_{o} - 0.166 \in (4.4)$$

Fig. 4.4 shows the validity of Eq. (4.4). The correlation is very good and as such this Equation can be used with

confidence for predicting  $y_{lL}$  in supercritical approach flows over longitudinal bar bottom-racks.

### 4.2 Study of The Coefficient of Discharge $C_d$ :

### 4.2.1 Parameters:

The pressure distribution at the inlet of the rack will in general be different from the hydrostatic pressure distribution— due to the curvature of the flow. In the extreme case of a sudden drop (and also a slot) it is known that the critical depth  $y_c$  occurs at about  $5y_e$  and at that section the flow is essentially parallel and the hydrostatic pressure distribution exists there. As such a section at a distance of  $5y_{1e}$  upstream from the inlet was chosen for defining the approach flow parameters. At this section the specific energy  $E_0$  was taken as  $E_0 = y_0 + \frac{V_0^2}{2g}$ . Assuming an orifice type flow through the rack with an operating head equal to the energy head  $E_0$  over the entire rack, a coefficient of discharge  $C_d$  through the longitudinal bar bottom—racks is defined as

$$C_{d} = \frac{Q_{D}}{BL \in \sqrt{2gE_{0}}}$$
 (4.5)

where  $Q_D^{}$  = diverted flow through rack. The possible variables influencing  $C_d^{}$  may be grouped as:

$$C_d = fn(V_o, y_o, B, L, D, S, g, )$$
, longitudinal slope (4.6)

Hence the dimensionless groups of variables will be

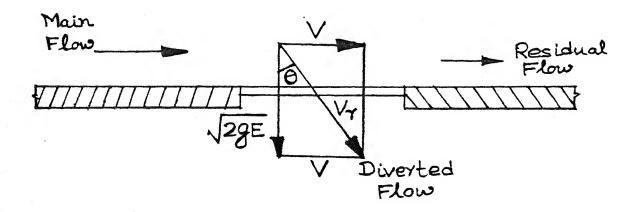

$$C_{d} = \text{fn} \left( \frac{V_{o}}{\sqrt{gy_{o}}}, \frac{V_{o}y_{o}}{V}, \frac{B}{y_{o}}, \frac{B}{L}, \frac{D}{S}, \frac{D}{B}, \text{longidutinal} \right)$$

For horizontal bottom-racks, longidudinal slope =0 and for two dimensional flow cases  $\frac{B}{y_0}$  may be considered to be an insignificant parameter. Out of the two rack parameters D/S is considered to be significant and the other viz, D/B can be considered to be insignificant especially for very low values of D/B. For turbulent flows  $\frac{V_0 y_0}{V}$  = Reynolds number of the approach flow being very high may be considered to have negligible effect over  $C_d$ . Hence for analysis in the practical ranges, the functional variation of  $C_d$  is taken as

$$C_{d} = fn \left[ F_{o}, \frac{D}{S}, \frac{B}{L} \right]$$
 (4.8)

If V = mean flow velocity in the channel, the resultant velocity  $V_r$  is given by  $V_r = \sqrt{V^2 + 2gE}$  as shown in Fig.A4.O5. The velocity through the rack, when assumed as an orifice flow, is directly proportional to  $\sqrt{2gE}$ , where E is the specific energy at any section over the rack. Also the parameter  $\frac{V^2}{2gE} = \tan^2\theta$  where  $\theta$  = angle of inclination of the resultant velocity  $V_r$  with the vertical. Hence greater the angle  $\theta$  lesser will be the effective area carrying the diverted flow. Hence lesser will be  $C_d$ . Thus  $\frac{V^2}{2gE}$  seem to be an important parameter affecting the  $C_d$ . This parameter can be represented as

$$\frac{V^2}{2gE} = \frac{V^2}{(2gy+V^2)} = \frac{1}{(1+2/F^2)}$$
 (4.9)

ig. A 4.05

Velocity Triangle of the Flow Diverting Through the Rack.

where F= Froude number of the flow at any section. For the purpose of analysis, the dimensionless parameter  $\frac{V_0^2}{2gE_0}$  can be taken to be representative of  $\frac{V_0^2}{2gE}$  for given rack and inlet conditions. In view of this, the parameter  $\frac{V_0^2}{2gE_0}$  is used in the place  $F_0$  in Eq (4.8) to represent  $C_d$  as

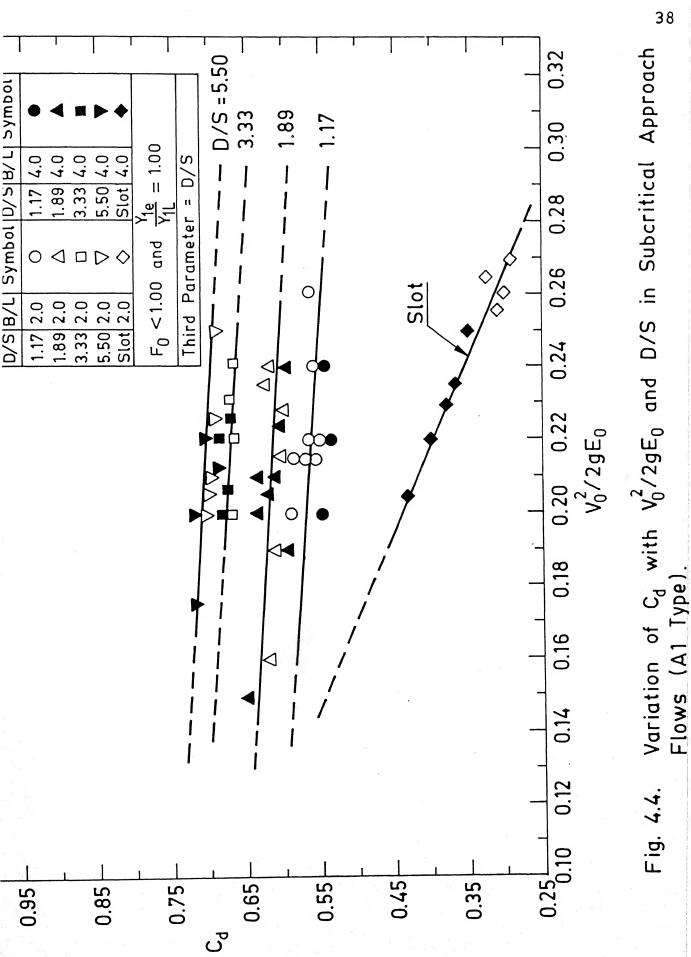

$$C_{d} = fn \left( \frac{V_{o}^{2}}{2gE_{o}}, \frac{D}{S}, \frac{B}{L} \right)$$
 (4.10)

It may be mentioned that a parameter similar to  $\frac{\sqrt{2}}{2gE_0}$  has also been used previously by Venkataraman, et al (4) and Ramamurthy, et al (6) to represent the approach velocity effect over the discharge coefficient through bottom-intakes. The term  $\frac{\sqrt{2}}{2gE}$  can be called as the Flow parameter for the rack. The parameter D/S is a measure of transverse contraction of the flow for a given opening area ratio. The parameter B/L is a measure of the two dimensionality of flow over the rack representing the possible effects of side walls.

The variation of  $C_{\mbox{\scriptsize d}}$  with the parameters given in Eq.(4.10) is analysed separately for Al,A3 and Bl types of flow.

# 4.2.2 $C_d$ in Al Flows:

For Al flows the variation of  $C_d$  with  $\frac{V_0^2}{2gE_0}$  by taking D/S as the third parameter is shown in Fig. 4.4. Four values of D/S in each of the two sets B/L =2.0 and 4.0 respectively are plotted in this Figure. Also plotted are the results of experiments of flow over a slot. It is seen

that for a given D/S, there is no effect of B/L and the value of  $C_d$  decreases very slowly with  $\frac{V_0^2}{2gE_0}$ . The trend is consistent for all four values of D/S tested. The variation of  $C_d$  for a slot is appropriately located at low values of D/S. However, for a slot, the effect of  $\frac{V_0^2}{2gE_0}$  is more pronounced, possibly due to the different nature of flow.

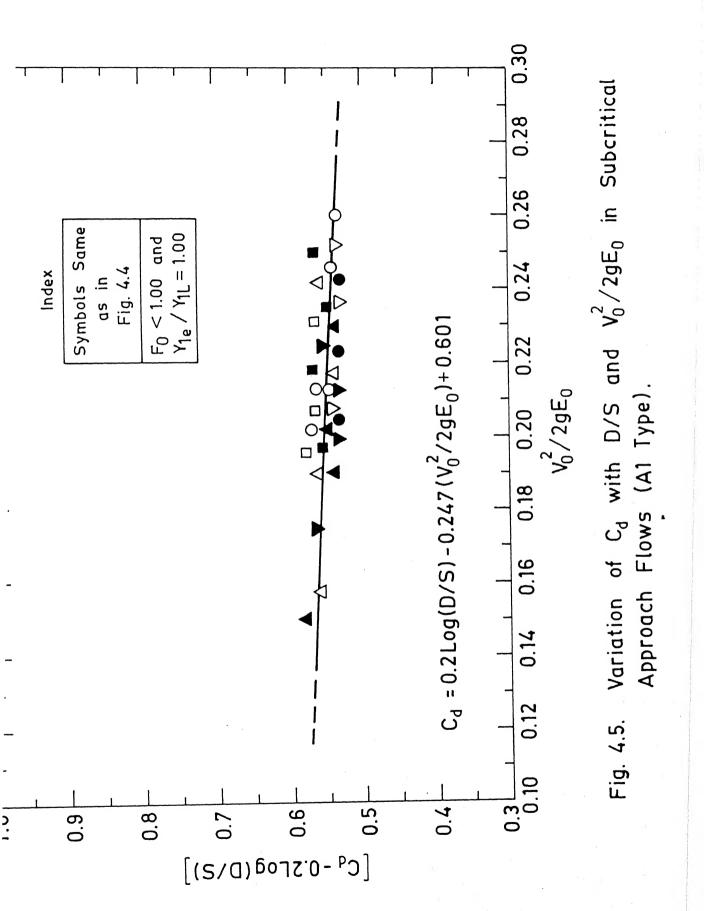

The variation of  $C_d$  for a given  $\frac{V_0^2}{2gE_0}$  was found to be related by a logarithmic relation as

$$C_d = 0.2 \text{ Log } (D/S) + 0.56$$
 (4.11)

within the range of D/S values tested (viz, D/S= 1.17 to 5.50). The best fit relation for the  $exp_e$ rimental data on Al flows was obtained as

$$C_d = 0.2 \text{ Log } (D/S)-0.247 \left(\frac{V_o^2}{2gE_o}\right) + 0.601 (4.12)$$

This is shown in Fig. 4.5 where [  $C_d$ -0.2 Log (D/S)] is plotted against  $\frac{V_0^2}{2gE_0}$  and all the data on Al flows are plotted, Eq. (4.12) is also shown in this Fig. It is interesting to observe the small scatters of data and hence the good correlation. As such, Eq.(4.12) can be taken to adequately represent the variation of  $C_d$  in Al flows for longitudinal bar bottom-racks. It may be noted that  $\frac{V_0^2}{2gE_0}$  has a very small effect on  $C_d$  in Al flows, as the term  $\frac{V_0^2}{2gE_0}$  will be within value of 0.33. Hence, the second term in Eq. (4.12) can be neglected within 5 percent error.

# 4.2.3 $C_d$ in A3 Flows:

For A3 flows  $C_d$  can be expected to be given by  $V_d^2$   $C_d = \text{fn} \left[ \frac{0}{2gE_0}, D/S, S_b \text{ and } B/L \right]$  (4.13)

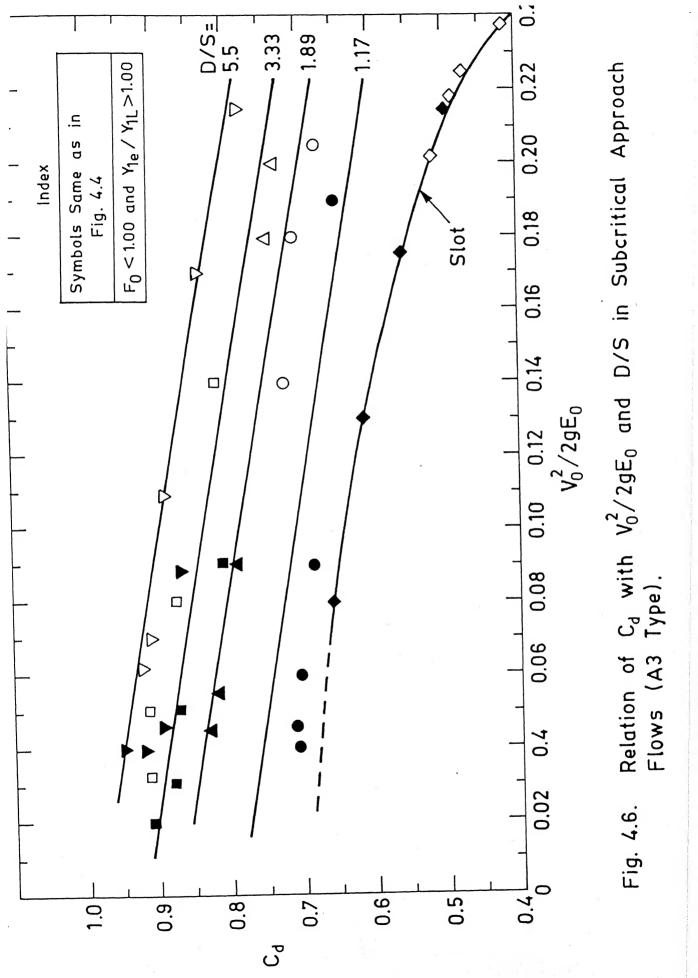

where  $S_b$  = submergence of the inlet =  $\frac{y_{1e}-y_{1L}}{y_{1e}}$ . For A3 flows the variation of  $C_d$  with  $\frac{v_0^2}{2gE_0}$  by taking D/S as third parameter is shown in Fig. 4.6. Four values of D/S in each of the two sets B/L = 2.0 and 4.0 respectively are plotted in this figure, the data covers a range of submergence  $S_b$  = 0.1 to 0.55. Also plotted are the results of experiments of flow over a slot. It is seen that for a given D/S, there is no effect of B/L and the value of  $C_d$  decreases with  $\frac{v_0^2}{2gE_0}$ . The trend is consistent for all four values of D/S tested. The variation of  $C_d$  for a slot is properly located at low values of D/S. Also there was no trend of variation of  $C_d$  with  $S_b$ . The variation of  $C_d$  for a constant  $\frac{v_0^2}{2gE_0}$  was found to be related by a logarithmic relation as

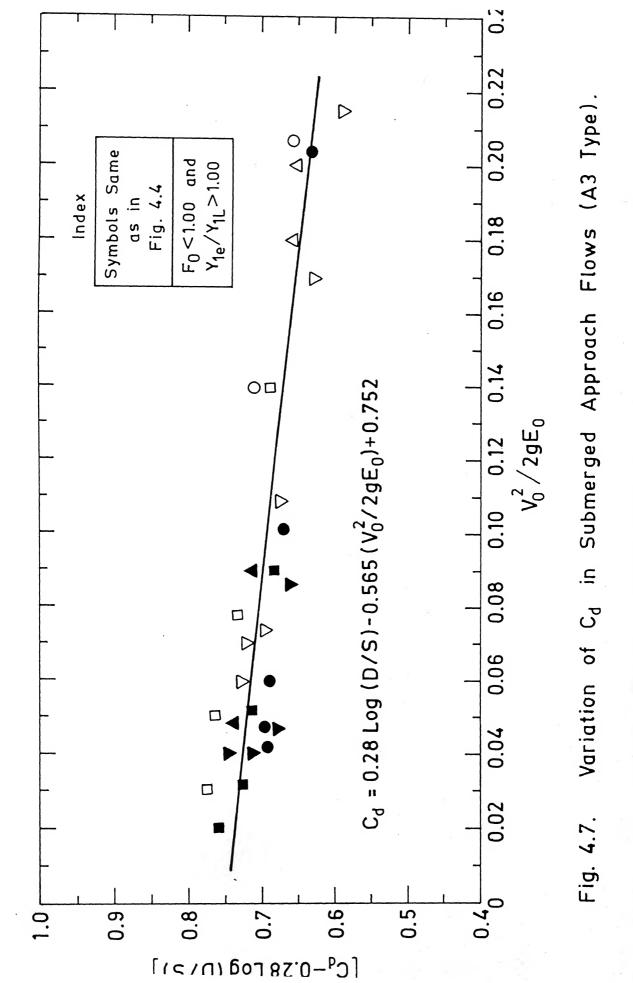

$$C_d = 0.28 \text{ Log } (D/S) + 0.57$$
 (4.14)

within the range of D/S values tested (viz, D/S =1.17 to 5.50). The best fit relation for the experimental data on A3 flows was obtained as

$$C_d = 0.28 \text{ Log}(D/S) - 0.565(\frac{V_o^2}{2gE_o}) + 0.752$$
 (4.15)

This is shown in Fig. 4.7 where  $[C_d-0.28 \text{ Log } (D/S)]$  is plotted against  $\frac{V_0^2}{2gE_0}$  and all the data on A3 flows are plotted. Eq.(4.15) is also shown. The maximum scatter of experimental

data was found to be  $\pm$  6%. Hence, being a satisfactory correlation Eq. (4.15) can be taken to adequately represent the variation of  $C_d$  in A3 flows over longitudinal bar bottom-racks for submergence factor  $S_b \leq 0.55$ . It may be noted that, compared to Al flows the values of  $C_d$  are higher in A3 flows. It is possible that at  $C_d$  is a weak function of  $S_b$  and at higher submergences Eq.(4.15) may have different coefficients.

# 4.2.4 $C_d$ in Bl flows:

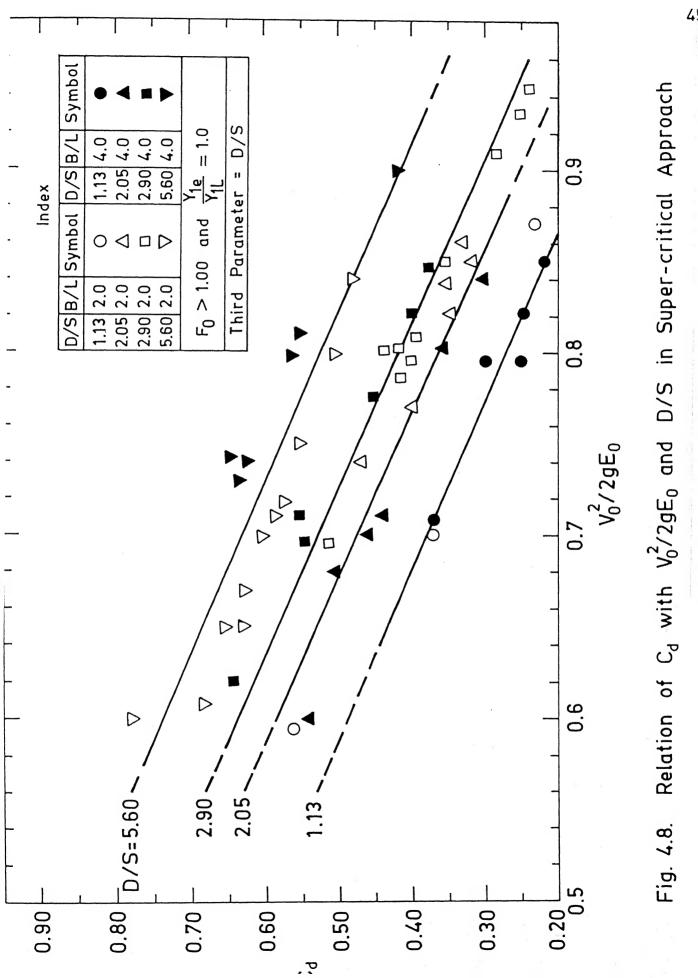

For BI flows the variation of  $C_d$  with  $\frac{V_0^2}{2gE_0}$  by taking D/S as third parameter is shown in Fig. 4.8. Four values of D/S in each of the two sets B/L = 2.0 and 4.0 respectively are plotted in this figure. It is seen that for a given D/S, there is no effect of B/L and the value of  $C_d$  decreases with  $\frac{V_0^2}{2gE_0}$ . The trend is consistent for all the four values of D/S tested. The variation of  $C_d$  for a constant  $\frac{V_0^2}{2gE_0}$  was found to be related by a logarithmic relation as

$$C_d = 0.36 \text{ Log (D/S)} + 0.29$$
 (4.16)

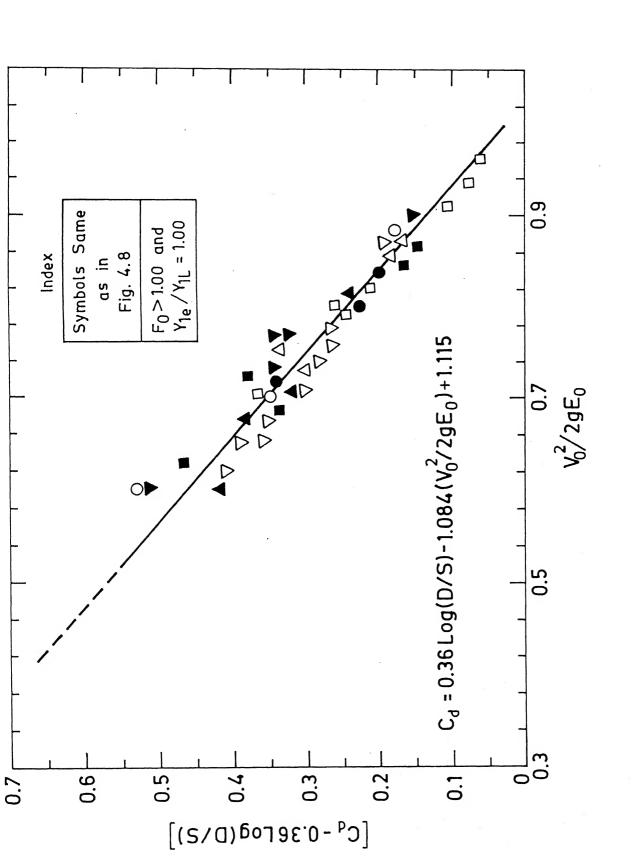

within the range of D/S values tested (viz, D/S = 1.13 to 5.60). The best fit relation for the experimental data on Bl flows was obtained as

$$C_d = 0.36 \text{ Log (D/S)-1.084 (} \frac{V_o^2}{2gE_o}) + 1.115$$
 (4.17)

This is shown in Fig. 4.9 where [  $C_d$ -0.36 Log (D/S)] is plotted against  $\frac{V_0^2}{2gE_0}$  and all the data on Bl flows are plotted. Eq.(4.17) is also shown in this Fig. The maximum scatter

of experimental data was found to be  $\pm$  10% with an average scatter of 3%, Hence, being a satisfactory correlation Eq. (4.17) can be taken to adequately represent the variation of  $C_d$  in Bl flows over longitudinal bar bottom-racks. It is noted that  $C_d$  values are affected considerably by the flow parameter  $V_0^2/2gE_0$ . For a given D/S ratio,  $C_d$  values rapidly decrease with increase in  $V_0^2/2gE_0$  i.e. with the increase in Froude number of the approach flow.

#### 4.3 Prediction of the Diversion Ratio:

### 4.3.1 Parameters

written as

While the diverted flow  $Q_D$  for a given rack and flow condition can be calculated by using  $C_d$ , it is useful for design purposes to directly correlate the diversion ratio to the rack and flow parameters. The diversion ratio of a bottom-rack is defined as the ratio of flow diverted through the rack  $Q_D$  to the total stream flow  $Q_S$  i.e.  $Q_D/Q_S$ . The pertinent variables influencing the  $Q_D$  through a horizontal longitudinal bottom-rack may be grouped as

$$Q_D = \text{fn} [Q_S, y_o, \mathcal{V}, g, B, L, D S]$$
 (4.18)  
Hence, the dimensionless parameters affecting  $\frac{Q_D}{Q_S}$  can be

 $\frac{Q_{D}}{Q_{S}} = \operatorname{fn}\left[\frac{L^{3}B^{2}q}{Q_{S}^{2}}, \frac{Q_{S}}{B\nu}, \frac{D}{S}, \frac{D}{B}, \frac{B}{L}, \frac{B}{V_{O}}\right]$ (4.19)

The dimensionless parameters in simplified form can be rewritten as

$$\frac{Q_{D}}{Q_{S}} = \text{fn} \left[ \frac{L}{Y_{C}}, R_{eo}, \frac{D}{S}, \frac{B}{L}, \frac{D}{B}, \frac{B}{Y_{O}} \right]$$
 (4.20)

where  $R_{eo}$  = Reynolds number of approach flow

 $y_c = upstream critical depth.$ 

For turbulent flows,  $R_{eo}$ , being very high, may be considered to have negligible influence on the gross characteristics of the phenomenon. Out of the two rack parameters D/S is considered to be significant and the other viz, D/B is considered not significant at very small values. Further by assuming the effect of aspect ratio  $\frac{B}{Y_{o}}$  to be insignificant in 2D flows, the diversion ratio is expressed as

$$\frac{Q_D}{\overline{Q}_S} = \operatorname{fn}\left[\frac{L}{Y_C}, \frac{D}{S}, \frac{B}{L}\right] \tag{4.21}$$

The parameter  $\frac{L}{\gamma_C}$  is a measure of the nature of approach flow and the size of the rack. It can be expected that the diversion ratio will increase with  $\frac{L}{\gamma_C}$ . The parameter D/S is a measure of transverse contraction of the flow for a given opening area ratio . The parameter B/L is a measure of the two dimensionality of the flow over the rack representing the possible effects of side walls. It may be mentioned that the parameter  $\frac{L}{\gamma_C}$  has been used by Venkataraman, et al (4) for representing the variation of diversion ratio of a slot.

The variation of the diversion ratio with the parameters as in Eq. (4.21) is analysed separately for Al and Bl flows.

4.3.2 
$$\frac{Q_D}{Q_S}$$
 in Al Flows

For AAl flows the variation of  $\frac{Q_D}{Q_S}$  with  $\frac{L}{\gamma_C}$  by taking D/S as third parameter is shown in Fig. 4.10. Four values of D/S in each of the two sets B/L =2.0 and 4.0 respectively are plotted in this figure. The value of  $\frac{B}{\gamma_0}$  in all the data was in the range 1.3-5.8. It can be observed that  $\frac{Q_D}{Q_S}$  is not affected by B/L for a given D/S and increases linearly with  $\frac{L}{\gamma_C}$ . Also, there is no specific effect of B/ $\gamma_0$ . The trend is consistent for all the four D/S values tested. It is observed that the curve drawn through the experimental points passed through the origin in all the four cases of D/S. This is consistent with the boundary condition  $Q_D$ =0 when L=0 i.e., when there is no opening, there is no flow diversion. For a constant D/S, the diversion ratio can be expressed as

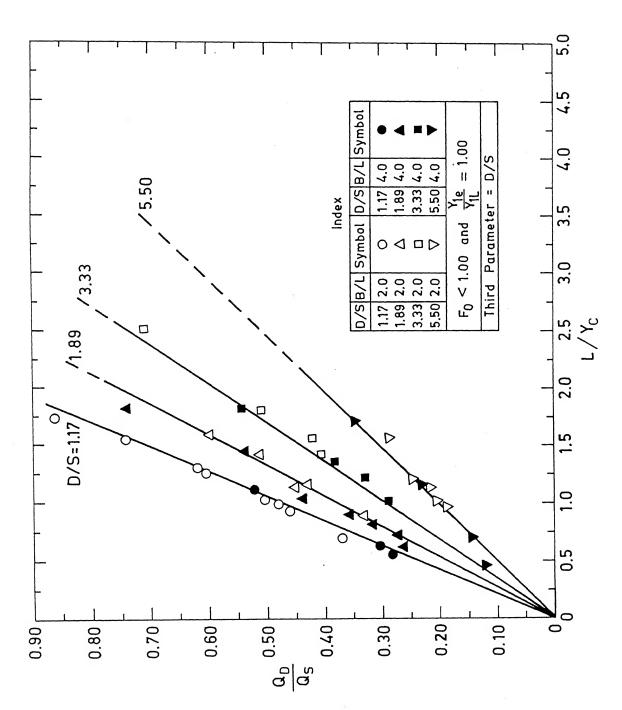

$$\frac{Q_D}{Q_S} = m_1 (L/\gamma_C) \tag{4.23}$$

The slope  $m_1$  is a function of D/S as seen in Fig. 4.10. The variation of  $m_1^*$  with D/S for Al flows is shown in Fig. 4.12 , from which  $m_1$  can be expressed as

$$m_1 = 0.51 - 0.41 \text{ Log } (D/S)$$
 (4.24)

Combining Eqs. (4.23) and (4.24)

$$\frac{Q_D}{Q_S} = [0.51 - 0.41 \text{ Log } (D/S)] \frac{L}{Y_C}$$
 (4.25)

Variation of Diversion Ratio in Subcritical Approach Flows (Al Type). Fig. 4.10.

The minimum length of rack to divert all the incoming flow,  $L_m$  is defined as the length causing 100% diversion. Hence, by putting  $\frac{Q_D}{Q_S}$  = 1.0 in Eq. (4.25)

$$L_{m_1} = \frac{Y_c}{[0.51-0.41 \text{ Log (D/S)}]}$$
 (4.26)

For a constant D/S, Eq. (4.25) is valid for  $\frac{L}{y_c} \leq \frac{L_{m_1}}{y_c}$  and for all  $\frac{L}{y_c} > \frac{L_{m_1}}{y_c}$  the  $\frac{Q_D}{Q_S}$  will obviously be unity.

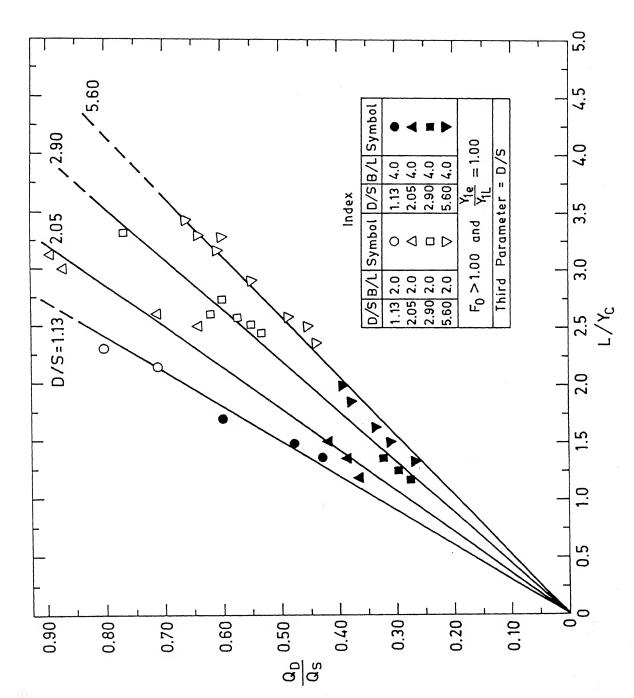

4.3.3  $\frac{Q_D}{Q_S}$  in Bl Flows

For Bl flows the variation of  $\frac{Q_D}{Q_S}$  with  $\frac{L}{y_c}$  by

taking D/S as third parameter is shown in Fig. 4.11. Four values of D/S in each of the two sets B/L =2.0 and 4.0 respectively are plotted in this figure. The value of  $\frac{B}{y_0}$  in all the data was in the range 6.98-15.38. It is seen that  $\frac{B}{L}$  has no effect over  $\frac{Q_D}{Q_S}$  for a given D/S while  $\frac{Q_D}{Q_S}$  increases linearly with  $\frac{L}{y_c}$ . Also,  $\frac{B}{y_0}$  has no distinct effect over the diversion ratio. The trend is consistent for all the four D/S values tested. Similar to Al flows, in this case also the variation of  $Q_D/Q_S$  with  $L/y_c$  is linear and can be expressed by Eq. 4.25, replacing  $m_1$  by  $m_2$ .

The slope  $m_2$  is a function of D/S as seen in Fig. 4.11. The variation of  $m_2^*$  with D/S for Bl flows is also shown in Fig. 4.12, from which  $m_2$  can be expressed as

$$m_2 = 0.36 - 0.26 \text{ Log (D/S)}$$
 (4.27)

Variation of Diversion Ratio in Super-critical Approach Flows (B1 Type). Fig. 4.11.

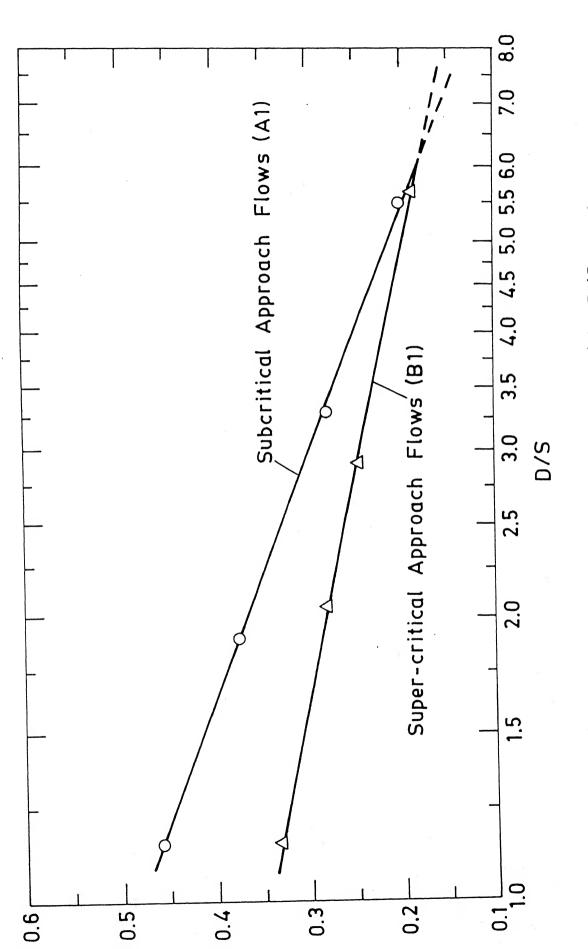

Fig. 4.12. Relation of m with D/S.

Combining Eqs. (4.23) and (4.27)

$$\frac{Q_{\rm D}}{Q_{\rm S}} = [0.36 - 0.26 \text{ Log (D/S)}] \frac{1}{Y_{\rm C}}$$
 (4.28)

Further the minimum length  $L_{m_{\widehat{2}}}$  in Bl flows can be represented  $\widehat{\mathbf{A}}$  as

$$L_{m_2} = \frac{y_c}{[0.36-0.26 \text{ Log}(D/S)]}$$
 (4.29)

As in Al flows, for a constant D/S, Eq.(4.28) is valid till  $\frac{L}{y_c} \leq \frac{L_{m_2}}{y_c}$  and for all  $\frac{L}{y_c} > \frac{L_{m_2}}{y_c}$ ,  $Q_D/Q_S$  will be unity. It is observed that for a given  $\frac{L}{y_c}$  and D/S, the diversion ratio is higher in Al flows than in Bl flows.

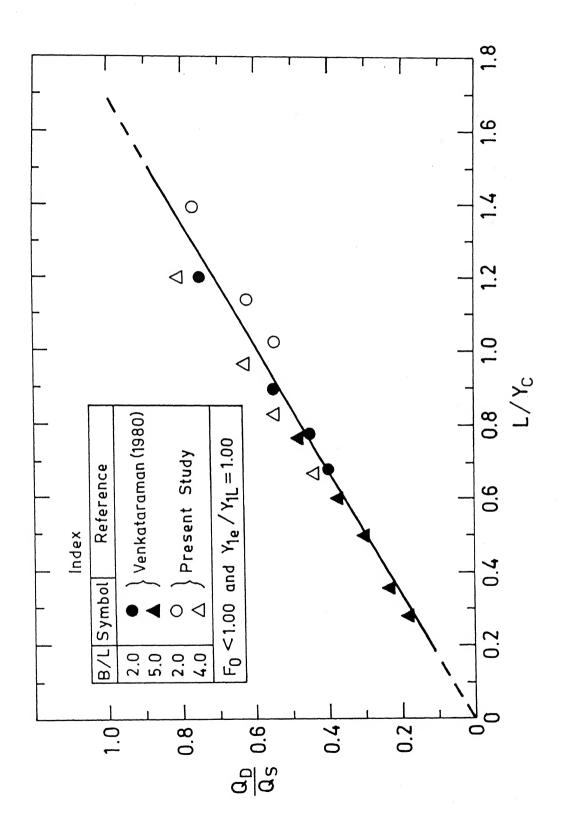

\* In Fig. 4.12, m=m<sub>1</sub> (for Al flows) and m=m<sub>2</sub> (for Bl flows). 4.3.4  $\frac{Q_D}{Q_S}$  in Al flows over a Slot:

For Al flows over a slot the variation of  $\frac{\mathsf{Q}_D}{\mathsf{Q}_S}$  with

 $\frac{L}{Y_C}$  is shown in Fig. 4.13. The experimental data of the present study for the two sets B/L = 2.0 and 4.0 along with the experimental data from Venkataraman (4) for B/L = 2.0 and 5.0 are plotted in this Figure. It is seen that  $\frac{B}{L}$  does not affect the diversion ratio distinctly. Diversion ratio varies linearly with  $\frac{L}{Y_C}$  and can be expressed as

$$\frac{Q_D}{Q_S} = 0.5883 \left( \frac{L}{y_C} \right) \tag{4.30}$$

From this equation for Al flows over a slot,  $\frac{L_m}{y_c}=1.7$ . The Eq.(4.30) is valid for  $\frac{L}{y_c} \leq \frac{L_m}{y_c}$  and for all values of

Variation of Diversion Ratio for a Slot in Sub-critical Approach Flows (A1 Type). Fig. 4.13.

 $\frac{L}{y_c}$  >  $\frac{L_m}{y_c}$  the diversion ratio will be unity, where  $L_m$ = minimum length of the slot required for 100% diversion.

### 4.4 Energy Loss Over the Rack:

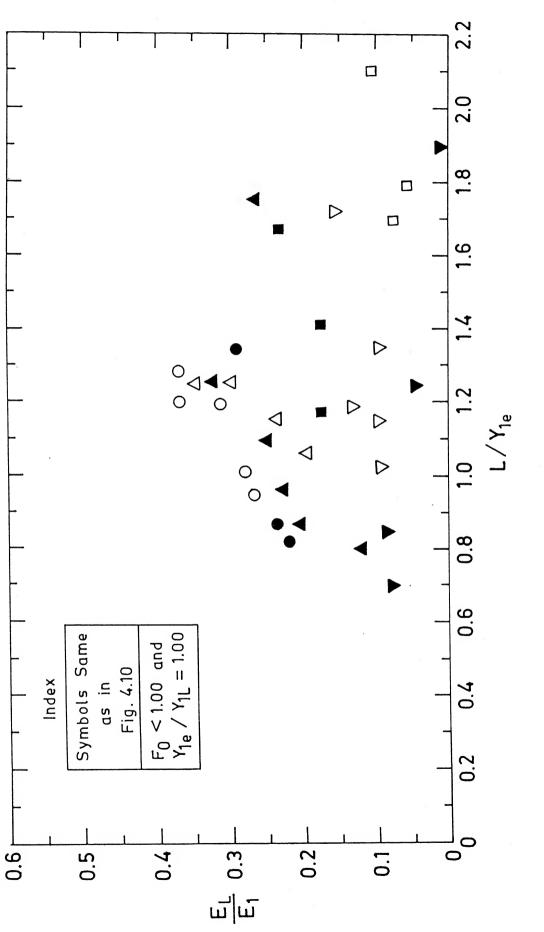

### 4.4.1 <u>Introduction</u>:

For determining the energy loss  $E_L$  over the rack, the specific energy at the inlet to the rack  $E_1$  was defined as  $E_1 = y_{1e} + \frac{V_1^2}{2g}$  by ignoring the correction for curvilinear flow over this section. Thus the energy loss over the horizontal rack can be approximated without serious error as

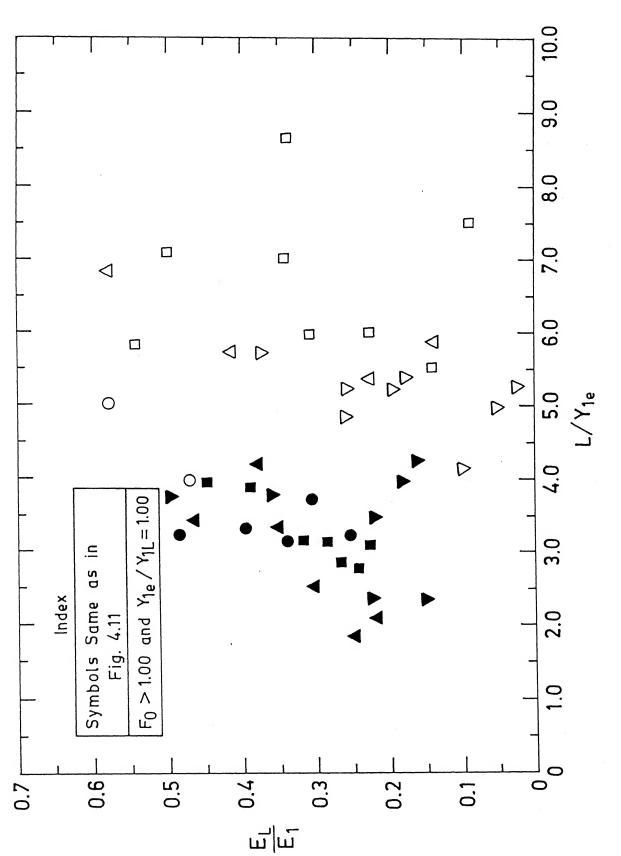

$$E_{L} = E_{1} - E_{2} = (y_{1e} + \frac{v_{1}^{2}}{2q}) - (y_{2e} + \frac{v_{2}^{2}}{2q})$$
 (4.31)

where suffix 2 represents the conditions at section 2. It is common in spatially varied flow analysis (for example Mostkow (3)) to assume the energy loss over the rack as negligibly small. As such, a study was made to find out the order of magnitude of the energy loss in the present investigation.

Plots of  $\frac{E_L}{E_l}$  vs  $\frac{L}{y_{le}}$  for Al and Bl flows are shown in Figs. 4.14 and 4.15 respectively. It is seen that in both these flows there is considerable energy loss even though there is no direct correlation with  $\frac{L}{y_{le}}$ . The average value of  $\frac{E_L}{E_l}$  in Al flows is around 15% while it is about 30% in Bl flows. Also it was found that  $\frac{E_L}{E_l}$  is not correlated with  $F_l$  in both Al and Bl flows.

Variation of Energy Loss Over the Rack in Subcritical Approach Flows (A1 Type) Fig. 4.14.

Variation of Energy Loss Over the Rack in Supercritical Approach Flows (B1 Type). Fig. 4.15.

In a simple model 
$$E_L$$
 was defined as 
$$E_L = K \frac{V_1^2}{2g} \eqno(4.32)$$

where K is the coefficient of energy loss. While an average value of K was obtained as 0.4 in both Al and Bl flows, there was considerable scatter and no distinct correlation with either  $F_1$  or  $L/y_{1e}$  could be obtained.

. In another model the energy slope  $\mathbf{S}_{\mathbf{e}} = \mathbf{E}_{\tilde{\mathbf{L}}}/\mathbf{L}$  was expressed as

$$S_e = fn (B,L, y_{le}, D, S)$$
 (4.33)

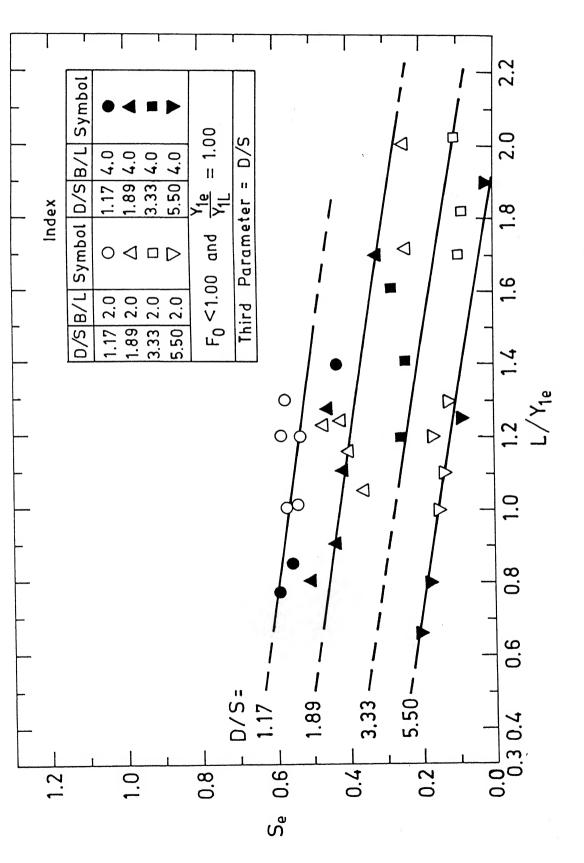

Groups of dimensionless variables affecting the variation of  $S_{\Delta}$  can be written as

$$S_e = fn \left(\frac{L}{y_{1e}}, \frac{D}{S}, \frac{B}{L}\right)$$
 (4.34)

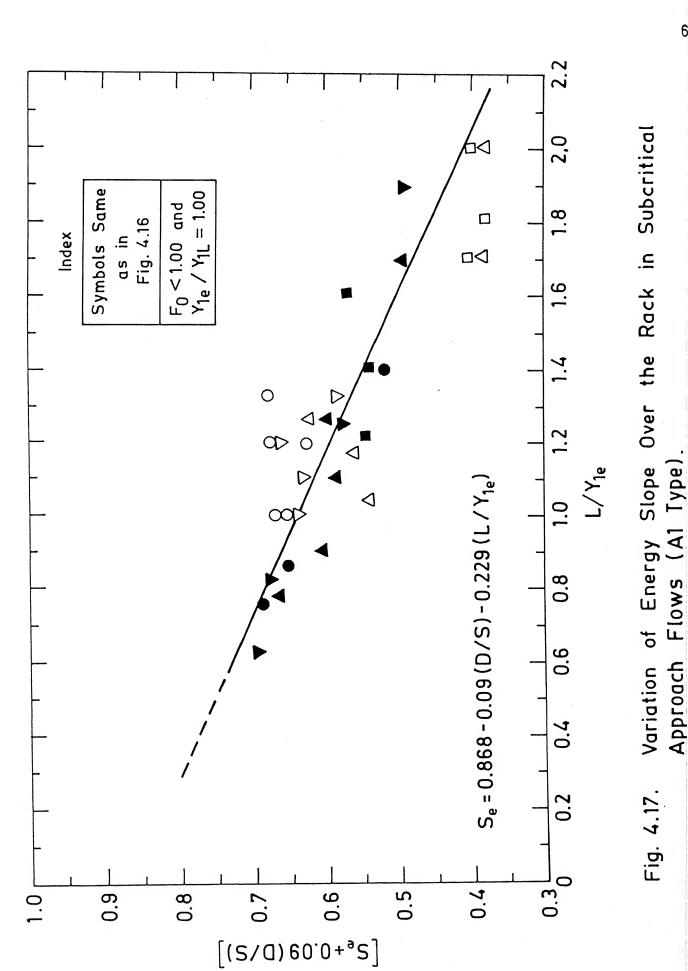

The variation of  $S_{\rm e}$  with the parameters as in Eq. (4.34) is analysed separately for Al and Bl flows.

## 4.4.2 S<sub>e</sub> in Al flows:

For Al flows the variation of  $S_e$  with  $\frac{L}{y_{le}}$  by taking D/S as the third parameter is shown in Fig. 4.16. Four values of D/S in each of the two sets B/L = 2.0 and 4.0 respectively are plotted in this figure. It is seen that for a given D/S there is no effect of B/L and the value of  $S_e$  decreases with  $\frac{L}{y_{le}}$ . The trend is consistent for all the four D/S values tested. The variation of  $S_e$  for a constant  $\frac{L}{y_{le}}$  was found to be related by a linear relation within the range of D/S values tested (viz,D/S=1.17 to 5.50) as

D/S in Relation of Energy Slope with  $L/Y_{le}$  and Subcritical Approach Flows (A1 Type). Fig. 4.16.

$$S_{A} = 0.785 - 0.09 (D/S)$$
 (4.35)

Using this the best fit relation for the experimental data on Al flows was obtained as

$$S_e = 0.868-0.09 (D/S)-0.229 (L/y_{1e})$$
 (4.36)

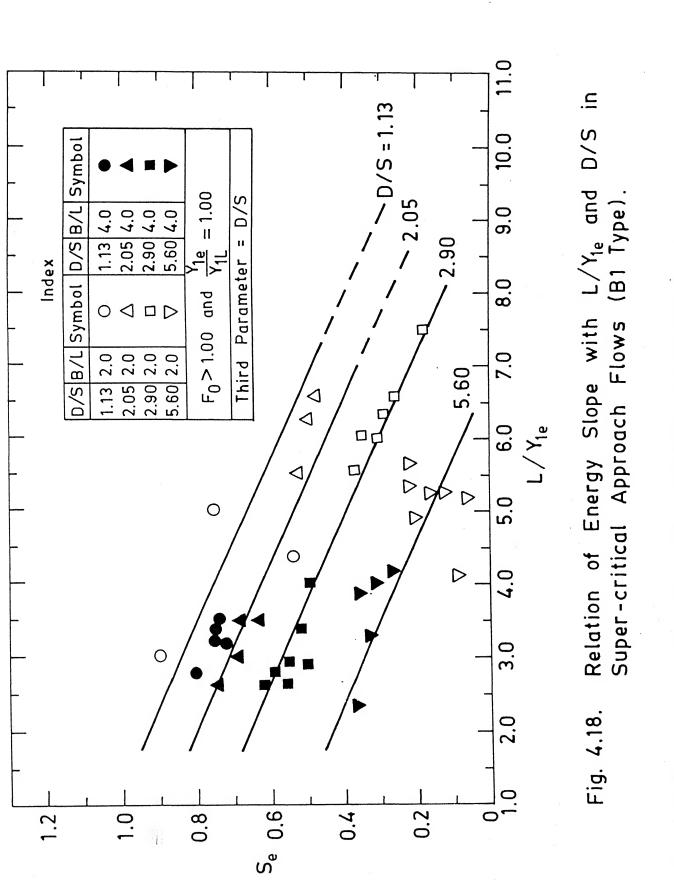

This is shown in Fig. 4.17 where  $[S_e + 0.09 \text{ (D/S)}]$  is plotted against  $\frac{L}{y_{le}}$  and all the data on Al flows are plotted. Eq. (4.36) is also shown in this Fig. The maximum scatter of the data was found to be  $\pm$  15% and the average scatter was about 5%. Hence, this equation can satisfactorily be used for the estimation of the energy slope in Al flows over lengitudinal bar bottom—racks.

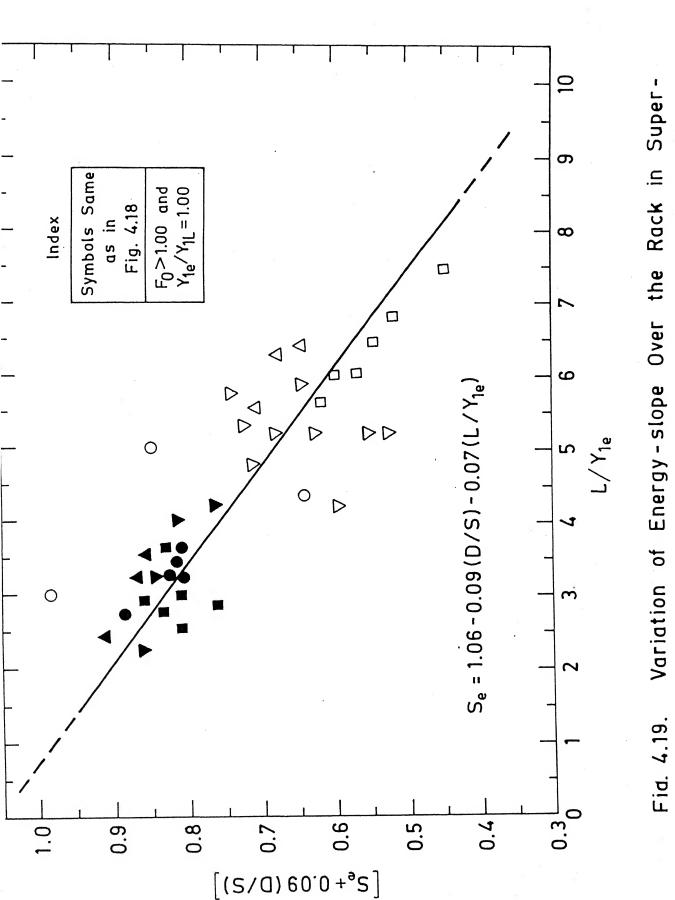

# 4.4.3 $S_e$ in Bl flows:

For Bl flows the variation of  $S_e$  with  $\frac{L}{y_{le}}$  by taking D/S as the third parameter is shown in Fig. 4.18. Four values of D/S in each of the two sets B/L=2.0 and 4.0 respectively are plotted in this figure. It is noted that for a given D/S there is no effect of B/L and the value of  $S_e$  decreases with  $\frac{L}{y_{le}}$ . The trend is consistent for all the four D/S values tested. The variation of  $S_e$  for a constant  $\frac{L}{y_{le}}$  was found to be related by a linear relation as

$$S_p = 1.01 - 0.09 (D/S)$$
 (4.37)

within the range of D/S values tested (viz, D/S = 1.13 to 5.60). The best fit relation for the experimental data on Bl flows was obtained as

Variation of Energy-slope Over the Rack in Super-

$$S_e = 1.06-0.09 (D/S) -0.075 (L/y_{le})$$
 (4.38)

This is shown in Fig. 4.19 where  $[S_e+0.09 \ (D/S)]$  is plotted against  $L/y_{le}$  and all the data on B1 flows are plotted. Eq. (4.38) is also shown. The maximum scatter of data is about 20% while the average scatter is roughly 8%. Hence, the equation (4.38) can satisfactorily be used for the estimation of the energy slope in B1 flows.

It is interesting to see that the coefficient of D/S in both the Eqns. (4.36) and (4.38) is same at 0.09. The energy slope, Se is smaller in Al flows, where the approach flow was subcritical, when compared to Bl flows. The range of parameters  $F_0$ ,  $F_1$ ,  $F_2$  and  $L/y_{le}$  used in the study are shown in Table 4.1.

Table 4.1 Range of Parameters used in the Study of  $S_{
m e}$ 

Al 0.60-0.85 1.1 - 1.5 1.1-1.45 0.67-2.1	Type o flow	of F <sub>o</sub>	$F_{1} = \frac{V_{1}}{V_{gy}}$	$F_{2} = \frac{V_{2}}{\sqrt{gy_{2e}}}$	L/y <sub>le</sub>	•
	Al	0.60-0.85	1.1 - 1.5	1.1-1.45	0.67-2.10	
B1 1.3 -5.4 1.6 - 6.1 4.8-6.5 2.0-8.0	Bl	1.3 -5.4	1.6 - 6.1	4.8-6.5	2.0-8.0	

It is obvious from the Table 4.1 that in Al flows, the inlet Froud number  $F_1$  varies in a very small range (1.1-1.5) and the range of flows  $F_1$  through  $F_2$  is also small. However, in Bl flow high Froude numbers as much as 6.5 were encountered

and account for higher energy losses. The Eqs.(4.36) and (4.38) must be considered as only approximate relationship. However, they underscore the magnitude of  $E_{\rm L}$  and their use is definitely an improvement over the assumption of zero energy loss.

## 4.4.4 Energy loss in A3 Flows:

The analysis of all experimental data on A3 flows shows that the percentage energy loss ( $\frac{E_L}{E_1}$ ) for most of the data lies within 2 to 4%. Also, the energy slope ( $S_e$ ) for mighty percent of data ranged from 0.05 to 0.15. The range of energy loss and the pertinent parameters of the flow observed in the study of A3 flows are shown in Table 4.2.

Table 4.2 Range of Energy Loss Parameters in A3 Flows:

Parameters		R	ange
	Min.	Max	Average
E.			
<u>-L</u> %	0.0	10.0	3.5
se	0.0	0.22	0.09
L/y <sub>le</sub>	0.15	0.90	0.40
s <sub>b</sub>	0.10	0.55	0.25

The range of  $E_L/E_1$  shown in Table 4.2 is quite small and no distinct variation of  $\frac{E_L}{E_1}$  or  $S_e$  could be observed with  $\frac{L}{V_1}$  and other parameters. More over, it is clear from

<sup>y</sup>le

Table 4.2 that the energy loss  $\frac{E_L}{E_1}$  as well as energy slope  $S_e$  are quite small. An average value for whole the data observed is given in the table with a view to show that majority of data were well within 2 to 4% energy loss.

Hence, for the analysis of A3 flows, the energy loss over the rack for  $S_b \leq 0.55$  can be taken as negligible for practical purposes.

## 4.5 Water Surface Profile Calculations:

In view of the above analysis, it is obvious that the energy loss over the rack particularly in Al and Bl flows can not be neglected. As such, Equations (2.4) and (2.12) suggested by Mostkow for water surface profile calculations along the rack by assuming constant specific energy all along it, are not justified to use.

The original equation of SVF with decreasing discharge for a rectangular, prismatic and horizontal channel by taking kinetic energy correction factor  $\alpha=1.0$ , can be represented as

$$\frac{dy}{dx} = \frac{Q_D q_{\frac{1}{2}}}{Q_D^2}$$

$$1 - \frac{Q_D^2}{Q_D^2}$$

$$1 - \frac{Q_D^2}{Q_D^2}$$
(4.39)

where  $S_e$  = Energy slope over rack;  $Q_D$  = Diverted flow through the rack;

and  $q_* = discharge per unit length of the rack and can be defined as$ 

$$q_* = \frac{Q_D}{L} = C_d B \in \sqrt{2gE_o} = Constant$$
 (4.40)

 $C_{
m d}$  can be calculated from equation (4.12) or (4.17) depending upon the type of flow Al or Bl respectively.

 $S_{\rm e}$  can be calculated from equation (4.36) or (4.38) depending upon the type of flow.

Then, the Eq. (4.39), after substituting the values of  $S_{\rm e}$  and  $q_{\rm *}$ , can be solved by a suitable numerical technique to obtain the water surface profile over the rack. Since, the energy loss in A3 flows, is negligibly small, Mostkow equations (2.4) and 2.12) can be used for water surface profile determination in this particular case.

#### CHAPTER V

#### CONCLUSIONS AND RECOMMENDATIONS

### 5.1 <u>Conclusions</u>:

A detailed experimental study has been made on the hydraulic behaviour of horizontal longitudinal bar bottom-racks, made of circular bars, in Al, A3 and Bl flows. Based on the study the following conclusions are drawn.

- 1. The variation of the limiting inlet depth ratio  $\frac{y_{1L}}{y_c}$  has been studied for Al and Bl flows separately. In Al flows it is found that  $\frac{y_{1L}}{y_c}$  varies with the opening area ratio and is not affected by B/L ratio of the rack, while in Bl flows  $\frac{y_{1L}}{y_c}$  depends upon the Froude number of approach flow  $F_o$  as well as  $\epsilon$ .
- 2. A coefficient of discharge  $C_d$  is defined as  $C_d = \frac{Q_D}{BL \in \sqrt{2g}E_o}$  Variation of  $C_d$  has been studied in Al,A3 and Bl flows separately. It is observed that  $C_d$  is a function of  $\frac{V_0^2}{2gE_o}$  and D/S ratio of the rack in all the three types of flows studied. The effect of B/L on  $C_d$  is found to be insignificant. The effect of the flow parameter  $\frac{V_0^2}{2gE_o}$  is found to be negligible in Al flows while it has a pronounced effect in Bl flows. The best fit Eqs. (4.12), (4.15) and (4.17) have been obtained for

estimation of  $C_d$  in Al,A3 and Bl flows respectively. It is found that the value of  $C_d$  in Bl flows for a given flow and rack parameter is higher than the corresponding value in Al flows. Also,  $C_d$  in A3 flows is higher than that in Al flows. Al and A3 flow over the limiting case of a rack (viz, a slot) are also studied.

- 3. The diversion ratio  $\frac{Q_D}{Q_S}$  is found to be a function of  $\frac{L}{Y_C}$  and  $\frac{D}{S}$  for Al and Bl flows. It is observed that the value of  $\frac{Q_D}{Q_S}$  is higher in Al flows than for corresponding value in Bl flows. The variation of the diversion ratio in Al and Bl flows are expressed by Eqs (4.25) and (4.28) respectively. The minimum length of the rack required for the whole diversion of the incoming flow has also been obtained from these equations.
- 4. For a slot in Al flows the diversion ratio is related with  $\frac{L}{y_c}$  by a simple equation (Eq. 4.30).
- 5. An attempt has been made for the determination of the energy loss over the rack. An average value of percentage energy loss with respect to inlet specific energy is determined as 15% and 30% in Al and Bl flows respectively. It is also observed that energy loss in A3 flows can be taken as essentially zero. The variation of  $S_e$  has been studied with  $\frac{L}{Y_{1e}}$  and  $\frac{D}{S}$  for both Al and Bl flows separately. It is found that the value of  $S_e$  in Bl flows is higher than the corresponding value in Al

- flows. Best fit equations (4.36) and (4.38) have been determined for estimating the energy slope  $S_{\rm e}$  in Al and Bl flows separately.
- equations for water surface profile determination, based on the assumption of zero energy loss seems to be erroneous. As such, using the energy slope Se calculated from corresponding equations obtained in the present study, in the original equation of SVF with decreasing discharge and solving it by any suitable numerical method, is the suggested approach for the determination of water surface profile over the rack. However the Mostkow equations can be used for determining water surface profiles in A3 flows without much error because of the negligible energy loss in this flow case.
- 7. Information of this study is useful in the design of trench weir intakes. A simple fortran program has been given in appendix II for determining the length of such trench weirs and compared with their original recommended design.

## 5.2 Recommendations:

Based on the literature review and the present study, the following further studies on this topic are recommended.

- Inclined lognitudinal bar bottom-racks need to be studied.
- The study could be extended to the perforated plate bottom-racks also.
- 3. Study could be extended for other shapes of bars namely Rectangular, stream lined etc to obtain efficient and economical bar geometry.
- 4. A more detailed study is needed for energy loss determination over the rack.

#### APPENDIX II

The main part of the design of trench weirs includes that or Longitudinal Bar Bottom-Racks. The present study indicates that the following field parameters are required for the the design of such racks:

- (i) The total stream flow, QS
- (ii) The diverted flow through the rack , QD
- (iii) The width of the rack /channel , B
- (iv) The depths , YO and Yie
- and (v) The diameter of the bar ,D and spacing , S between the bars.

The spacing can be chosen on the basis of the size of the sediment present in the stream.

with the suggested correlations one can use the above parameters to calculate the length of the rack. A simple Fortran program has been developed and given on the next page. The length calculated from this program with the available data for BANU and PARAI trench weirs alongwith their recommended length is given in Table I

TABLE I Comparision of design lenths.

Weirs	Length (m) calculated	Length (m)

TO STATE SHIPS WHEN MADES THESE COURS RATHER STATES AND AND AND	والم المال	THE THE REAL PLANS AND THE SENS AND SENS AND SENS AND THE SENS AND SENS AND THE SENS AND SENS AND THE SENS AND
BANU	1.1	2.0
PARAI	1.5	2.0

PROGRAM RACK

TRENCH WEIR -- RACK DESIGN

THE FOLLOWING PROGRAM CALCULATES THE LENGTH(L1) OF A BOTTOM KACK FOR WHICH APPROACH FLOW(QS), DIVERTED FLOW(QD) THROUGH RACK, YV, Y1e, DIAMETER(D) OF BARS, SPACING (S) BETWEEN THE BARS AND WIDTH(B) OF CHANNEL IS KNOWN. HERE YO IS DEPTH AT A DISTANCE '5Y1e'FROM U/S BRICH OF RACK &Y1e IS U/S BRINK DEPTH.

REAL L,L1 READ(21,\*) OS,QD,Y0,Y1e,D,S,B V0=QS/(B\*Y0) E0=Y0+((QS\*QS)/(19.62\*B\*B\*Y0\*Y0)) EPS=(S/(D+S))

THE OPEN AREA RATIO "EPS" HAS BEEN MULTIPLIED BY 0.45 BY CONSIDERING 10% REDUCTION DUE TO FRAME WORK AND 50% DUE TO CLOGGING TO GET " EPS1".

EPS1=0.45\*EPS
